Neurologic disorders are prevalent in HIV-positive outpatients in the Asia-Pacific region

ABSTRACT

Background: A total of 8.3 million HIV-positive people live in the Asia-Pacific region. The burden of HIV-associated neurocognitive impairment and asymptomatic sensory neuropathy in this region is unknown.

Methods: Between July 2005 and March 2008, we undertook a cross-sectional study of 10

Neurological disorders were prevalent in the Asia-Pacific region

HIV Dementia & Neurological Disorders- Intermittent and Early Treatment

SMART and START Neurology Sub studies

International RCTs to determine benefits of
intermittent ART (SMART n=292) and
immediate vs deferred ART (START n=592)

- ❖ CV risk factors play a key role in cognitive impairment in PLWH
- ❖ Immediate vs deferred ART was not associated with improved neurocognitive function

Cardiovascular risk factors associated with lower baseline cognitive performance in HIV-positive persons

OBJECTIVE: To determine factors associated with baseline neurocognitive performance in HIV-infected participants enrolled in the Strategic Management of Antiretroviral Therapy (SMART) neurocognitive study.

DESIGN: Prospective study from Australia, South Africa, Brazil, and Thailand was administered a SMART neurocognitive study.

SETTING: Participants from Australia, South Africa, Brazil, and Thailand were administered a SMART neurocognitive study.

MEASUREMENTS AND MAIN RESULTS: The SMART neurocognitive study was administered a SMART neurocognitive study.

CONCLUSIONS: The SMART neurocognitive study was administered a SMART neurocognitive study.

KEYWORDS: HIV, neurocognitive, cardiovascular, cognitive performance, HIV-positive persons.

INTRODUCTION: HIV infection is associated with a higher risk of cardiovascular disease (CVD) and cognitive impairment. The SMART neurocognitive study was administered a SMART neurocognitive study.

CONCLUSIONS: The SMART neurocognitive study was administered a SMART neurocognitive study.

CONCLUSIONS: The SMART neurocognitive study was administered a SMART neurocognitive study.

KEYWORDS: HIV, neurocognitive, cardiovascular, cognitive performance, HIV-positive persons.

No neurocognitive advantage for immediate antiretroviral treatment in adults with greater than 500 CD4+ T-cell counts

Early Antiretroviral Therapy

Research

Original Investigation

Influence of the Timing of Antiretroviral Therapy on the Potential for Normalization of Immune Status in Human Immunodeficiency Virus 1-Infected Individuals

Jason F. Okulicz, MD, Tuan Li, MD, DPH, Brian K. Agan, MD, Josef C. Menegozzi, MD, Michael L. Landrum, MD, Edwin Wright, MD, Matthew J. Dolan, MD, Anwarul Haque, MD, Thomas W. Ferguson, MD, Corey M. Smith, MD, Douglas D. Richman, MD, Susan J. Little, MD, Robert A. Clark, MD, Weijiang He, MD, Junhui Xie, MD, and Susan J. Little, MD

IMPORTANCE: In individuals with human immunodeficiency virus 1 (HIV-1) infection who are receiving antiretroviral therapy (ART), factors that promote full immune recovery are not well characterized.

OBJECTIVE: To investigate the influence of the timing of ART relative to HIV-1 infection on normalization of CD4⁺ T-cell counts, AIDS risk, and immune function.

DESIGN, SETTING, AND PARTICIPANTS: Participants in the observational US Military HIV Natural History Study with documented estimated dates of seroconversion (ES) who achieved viralologic suppression with ART were evaluated. Markers indicative of immune activation, dysfunction, and responsiveness were determined. Response to hepatitis B virus (HBV) vaccine, an indicator of *in vivo* immune function, were also assessed. The timing of ART was indicated to the ES and entry into the cohort. The CD4⁺ counts in HIV-1-uninfected populations were surveyed.

MAIN RESULTS AND RELEVANCE: Normalization of CD4⁺ counts to 900 cells/ μ L or higher, AIDS development, HBV vaccine response, as well as T-cell activation, dysfunction, and responsiveness.

RESULTS: The median CD4⁺ count in HIV-1-uninfected populations was approximately 900 cells/ μ L. Among 1195 HIV-1-infected participants, CD4⁺ normalization was achieved in 38.4% vs 28.3% of those initiating ART within 12 months vs after 12 months from the ES ($P < .005$). Incrementally higher CD4⁺ recovery (>500, 500-899, and >900 cells/ μ L) was associated with decrease decreases in AIDS risk and reversion of markers of immune activation, dysfunction, and responsiveness to levels approximating those found in HIV-1-uninfected persons. Participants with CD4⁺ counts of 500 cells/ μ L or higher at study entry (adjusted odds ratio [aOR], 2.05; 95% CI, 1.51-2.64; $P < .005$) or ART initiation (aOR, 4.08; 95% CI, 1.84-9.30; $P < .001$) had significantly increased CD4⁺ normalization rates compared with other participants. However, even among individuals with a CD4⁺ count of 500 cells/ μ L or higher at both study entry and before ART, the odds of CD4⁺ normalization were 80% lower in those initiating ART after 12 months from the ES and study entry (aOR, 0.20; 95% CI, 0.07-0.53; $P < .001$). Initiation of ART within 12 months of ES was associated with a significantly lower risk of AIDS (OR vs 1.3% $P < .005$), reduced T-cell activation (percent CD4⁺HLA-DR⁺ effector memory T cells, 12.0% vs 16.6%; $P < .03$), and increased responsiveness to HBV vaccine (67.9% vs 50.5%; $P < .03$).

CONCLUSIONS AND RELEVANCE: Deferral of ART beyond 12 months of the ES diminishes the likelihood of restoring immunologic health in HIV-1-infected individuals.

Enhanced CD4⁺ T-Cell Recovery with Earlier HIV-1 Antiretroviral Therapy

Tuan Li, M.D., Dr.P.H., Edwin J. Wright, M.D., Corey M. Smith, M.D., Weijiang He, M.D., Gabriel Catano, M.D., Jason F. Okulicz, M.D., Jason A. Young, Ph.D., Robert A. Clark, M.D., Douglas D. Richman, M.D., Susan J. Little, M.D., and Sunil K. Ahuja, M.D.

ABSTRACT

BACKGROUND: The relationship between the timing of the initiation of antiretroviral therapy (ART) after infection with human immunodeficiency virus type 1 (HIV-1) and the recovery of CD4⁺ T-cell counts is unknown.

METHODS: In a prospective, observational cohort of persons with acute or early HIV-1 infection, we determined the trajectory of CD4⁺ counts over a 48-month period in partially overlapping study sets: study set 1 included 384 participants during the time window in which they were not receiving ART and study set 2 included 211 participants who received ART soon after study entry or sometime thereafter and had a suppressed plasma HIV viral load. We investigated the likelihood and rate of CD4⁺ T-cell recovery to 900 or more cells per cubic millimeter within 48 months while the participants were receiving viral-load-suppressive ART.

RESULTS: Among the participants who were not receiving ART, CD4⁺ counts increased spontaneously, soon after HIV-1 infection, from the level at study entry (median, 495 cells per cubic millimeter; interquartile range, 383 to 623), reached a peak value (median, 760 cells per cubic millimeter; interquartile range, 573 to 987) within approximately 4 months after the estimated date of infection, and declined progressively thereafter. Recovery of CD4⁺ counts to 900 or more cells per cubic millimeter was seen in approximately 48% of the participants who initiated ART earlier (64 months after the estimated date of HIV infection) as compared with approximately 34% of participants who initiated ART later (4 months) (both $P < .001$). After adjustment for whether ART was initiated when the CD4⁺ count was 500 or more cells per cubic millimeter or less than 500 cells per cubic millimeter, the likelihood that the count would increase to 900 or more cells per cubic millimeter was lower by 60% (odds ratio, 0.35), and the rate of recovery was slower by 56% (rate ratio, 0.44), if ART was initiated later rather than earlier. There was no association between the plasma HIV RNA level at the time of initiation of ART and CD4⁺ T-cell recovery.

CONCLUSIONS: A transient, spontaneous restoration of CD4⁺ T-cell counts occurs in the 4-month time window after HIV-1 infection. Initiation of ART during this period is associated with an enhanced likelihood of recovery of CD4⁺ counts. (Funded by the National Institute of Allergy and Infectious Diseases and others.)

HIV Seroconversion Cohort (n=468)

❖ ART within vs > 4 months of seroconversion led to CD4+ normalization* in 64% vs 34% of people, respectively

HIV Seroconversion Cohort (n=1119)

❖ ART within vs > 12 months of seroconversion was associated with lower risk of AIDS, T-cell activation and HBV responsiveness

Antiretroviral Initiation at ≥ 800 CD4⁺ Cells/mm³ Associated With Lower Human Immunodeficiency Virus Reservoir Size

Thomas A. Rasmussen,^{1,2} Sarah E. Rhee,³ Lucinda K. Kwan,⁴ Michael J. Vjecha,⁵ Heather Nelson,^{6,7} Lucinda Le,⁸ Agnieszka Wroble,⁹ Judy Chang,¹ Sarah Palmer,¹⁰ Paolo Antinori,¹¹ Mary Wanyenze,¹² Robin Wood,¹³ Charles David Forster,¹⁴ Emily Pilley,¹⁵ Renee Waggoner,¹⁶ Alberto Luchini,¹⁷ Jose Hilliges,¹⁸ Kelly Pittman,¹⁹ Clara Diaz,²⁰ Joseph Lederman,²¹ Jonathan Ezzell,²² Esther Eshengrey,²³ Frances Finkel,²⁴ Cecilia Karon,²⁵ Katie Fisher,²⁶ Christina Chang,^{27,28} Sharon E. Lewin,^{29,30} and Christine A. Wiegman^{31,32}

Background. Identifying factors that determine the frequency of latently infected CD4⁺ T cells on antiretroviral therapy (ART) may inform strategies for human immunodeficiency virus (HIV) cure. We investigated the role of CD4⁺ count at ART initiation for HIV persistence on ART.

Methods. Among participants of the Strategic Timing of Antiretroviral Treatment Study, we enrolled people with HIV (PWH) who initiated ART with CD4⁺ T-cell counts of 500–599, 600–799, or ≥ 800 cells/mm³. After 36–44 months on ART, the levels of total HIV DNA, cell-associated integrated HIV RNA (CA-US HIV RNA), and two long terminal repeat HIV DNA in CD4⁺ T cells were quantified and plasma HIV RNA was measured by single-copy assay. We measured T-cell expression of Human Leucocyte Antigen II (HLA-DR), programmed death 1, and phosphorylated signal transducer and activator of transcription-5 (pSTAT5). Virological and immunological measures were compared across CD4⁺ strata.

Results. We enrolled 146 PWH: 36 in the 500–599, 60 in the 600–799, and 50 in the ≥ 800 CD4 strata. After 36–44 months of ART, total HIV DNA, plasma HIV RNA, and HLA-DR expression were significantly lower in PWH with CD4⁺ T-cell count ≥ 800 cells/mm³ at ART initiation compared with 600–799 or 500–599 cells/mm³. The median level of HIV DNA after 36–44 months of ART was lower by 70% in participants initiating ART with ≥ 800 vs 500–599 cells/mm³ [median (interquartile range)]: 16.3 (3.1–117.6) vs 48.4 (13.7–213.1) copies/cell/mL cells, respectively. Higher pSTAT5 expression significantly correlated with lower levels of HIV DNA and CA-US HIV RNA. Virological measures were significantly lower in females.

Conclusions. Initiating ART with a CD4⁺ count ≥ 800 cells/mm³ compared with 500–799 or 500–599 cells/mm³ was associated with achieving a substantially smaller HIV reservoir on ART.

Keywords: HIV; HIV reservoir; antiretroviral therapy; HIV cure.

Despite long-term virological suppression with antiretroviral therapy (ART), human immunodeficiency virus (HIV) persists in long-lived and proliferating CD4⁺ T cells [1]. Because latently infected cells constitute the main barrier to a cure, identifying factors that determine their frequency may provide insights into HIV cure strategies. Initiating ART early (eg, during seroconversion, within 6 or 12 months of infection) is associated with a lower frequency of latently infected CD4⁺ T cells [ie, lower HIV reservoir size] (2–11). Later dates of cell-associated HIV DNA [12], better CD4⁺ and CD8⁺ T-cell recovery [13–15], and better preserved B- and T-cell function

Know the science and the politics of science- *What can you really offer people?*

Pregnancy and syphilis¹ are ancient health conditions

- ❖ *No vaccines for pregnancy, syphilis or HIV infection*
- ❖ *No cure for HIV*
- ❖ *Prevention is available for pregnancy, syphilis and HIV but it can be withheld*
- ❖ *Treatment is available for HIV but it too can be withheld, as can abortion*
- ❖ *Pregnancy can be enforced*

***Wise to be humble
if what we have to
offer is modest and
may change with
the political times***

Science asks but it also gives

The propensity for suffering in humans and all creatures is enormous

The key driver of our behaviour throughout life is to move away from suffering and towards peace

Science rewards the clinician's endeavours and relieves people's suffering, hence it fosters peace

Neurologic disorders are prevalent in HIV-positive outpatients in the Asia-Pacific region

ABSTRACT

Background: A total of 8.3 million HIV-positive people live in the Asia-Pacific region. The burden of HIV-associated neurocognitive impairment and symptomatic sensory neuropathy in this region is unknown.

Methods: Between July 2005 and March 2006, we undertook a cross-sectional study at 10 sentinel sites within eight Asia-Pacific countries to determine the prevalence of moderate to severe HIV-related neurocognitive impairment and symptomatic sensory neuropathy. We clinically assessed and administered sensitive neuropsychological and peripheral neuropathy screening tools to 658 patients infected with HIV. Univariate and logistic regression analyses were applied to the data.

Results: The results showed that 76 patients (11.7%) [95% CI 9.3–14.2] were significantly neurocognitively impaired, 235 patients (36.4%) [95% CI 32.7–40.2] were depressed, and 126 patients (19.7%) [95% CI 16.6–22.8] had either definite or probable symptomatic sensory neuropathy. 69% of this last group had exposure to stavudine, didanosine, or zalcitabine. Several potential confounders including depression [OR 1.49, 95% CI 0.88–2.51, $p = 0.11$] and prior CNS AIDS illness [OR 1.28, 95% CI 0.50–2.89, $p = 0.54$] were not significantly associated with neurocognitive impairment.

Conclusions: A total of 12% of patients had moderate to severe HIV-related neurocognitive impairment, 20% of patients had symptomatic sensory neuropathy, and 36% of patients had evidence of depression. This study provides a broad regional estimate of the burden of HIV-related neurologic disease and depression in the Asia-Pacific region. *Neurology* 2006;71:63–69
