## Applications are open now for \$10,000 per annum supplementary scholarships for commencing PhD students

The Mount Lofty Ranges (MLR) in South Australia represent one of Australia's most heavily cleared and fragmented woodland ecosystems. Although remnant woodland ecosystems in the MLR still provide an important refuge for birds, the abundance of many woodland-specialist species is declining.

The Bob Croser Woodland Recovery Project will support research activities aimed at better understanding the optimal habitat reconstruction for declining bird species, how to best engage community and landholders in the recovery effort, and priority species-specific objectives for guiding restoration actions and monitoring the recovery of these critical but endangered species and ecosystem.

PhD projects are now available with the aim to achieve high-impact outcomes for bird recovery across the MLR in three priority research areas: :

Policy, investment, and  
landowner motivation

Understanding the requirements  
of bird populations to reverse  
declines

Quality habitat and vegetation:  
What should we plant where?
