

# Derivation and Validation of a Mechanically Consistent Continuum Damage Model for Brittle Composite Materials

Claudio Findeisen and Jörg Hohe Fraunhofer Institute for Mechanics of Materials IWM, Wöhlerstraße 11, 79108 Freiburg, Germany

### **Continuum Damage Mechanics of Brittle Anisotropic Materials** Motivation

- Damage modeling of brittle Ceramic Matric Composites (CMCs)
  - Stiffness degradation caused by microcracks due to mechanical or thermal loading
  - Due to the (woven) microstructure anisotropic damage evolution and effect
  - Damage effect is deactivated due to crack closure for "compressive" loading
  - Small amount of plastic deformation possible
- <u>Damage deactivation</u> with a continuous stress-strain relation [Chaboche 1993]
- Mechanically consistent if stiffness decreases by damage [Wulfinghoff2017]:

 $\varphi(\varepsilon, D) \ge \varphi(\varepsilon, D + dD)$  for all admissible  $\varepsilon, D, dD$ 

→ For most Models not fulfilled [Lemaitre 1996, Chaboche 2001,...]

Stress-strain behavior of a damaged brittle composite material

# **Continuum Damage Mechanics of Brittle Anisotropic Materials**

#### Model Formulation

Model Validation by Homogenization Results

 $90^{\circ}$  $120^{\circ}$  $60^{\circ}$  $150^{\circ}$  $30^{\circ}$  $300_{0^{\circ}}$ 100 $180^{\circ}$ 330°  $210^{\circ}$  $300^{\circ}$  $240^{\circ}$  $270^{\circ}$  $L_0(\omega)$  - Undammaged State  $\tilde{L}(\omega)$  - From Homogenization  $L(\omega)$  - Model 1  $L(\omega)$  - Model 4  $L(\omega)$  - Chaboche Model

- Model formulation
  - Neglects plastic deformation (1. Step)
  - Linear damage effect
  - Based on an invariant representation with orthotropic Invariants  $I_1, \ldots, I_{18}$
  - Reduction by restricting the damage state D to in-plane damage
  - Reduction by the damage growth criterion
  - Mechanically consistent damage effect model with 6 Material Parameters
  - Damage deactivation that results in a continuous (C<sup>0</sup>) stress-strain relation
- Model validation by virtual test data using simple homogenization approach (dilute crack distribution in anisotropic matrix)

# **Continuum Damage Mechanics of Brittle Anisotropic Materials**

#### Model Formulation

#### Damage Deactivation by closed microcracks

 $90^{\circ}$  $120^{\circ}$  $60^{\circ}$  $150^{\circ}$  $30^{\circ}$  $300 \\ 0^{\circ}$ 100 $180^{\circ}$ 330° 210°  $240^{\circ}$  $300^{\circ}$  $270^{\circ}$  $L_0(\omega)$  - Undammaged State  $L(\omega)$  with  $g_1 < 0, g_2 < 0$  $L(\omega)$  with  $q_1 < 0, q_2 > 0$  $L(\omega)$  with  $g_1 > 0, g_2 > 0$ 

- Model formulation
  - Neglects plastic deformation (1. Step)
  - Linear damage effect
  - Based on an invariant representation with orthotropic Invariants  $I_1, \ldots, I_{18}$
  - Reduction by restricting the damage state D to in-plane damage
  - Reduction by the damage growth criterion
  - Mechanically consistent damage effect model with 6 Material Parameters
  - Damage deactivation that results in a continuous (C<sup>0</sup>) stress-strain relation
- Model validation by virtual test data using simple homogenization approach (dilute crack distribution in anisotropic matrix)
