AI-based Imaging Biomarkers for Drug Evaluation Trials

Berend Stoel

Division of Image Processing, Department of Radiology

LEIDEN UNIVERSITY MEDICAL CENTER

COI: Bristol-Myers Squibb and Pfizer contributed to the presented research project on rheumatoid arthritis. BS is consultant for ClinFact, Clario, Medpace, CSL Behring, Talecris, Kamada, BeamTx and Takeda.

Imaging Biomarkers in Drug Evaluation Trials

Imaging biomarker

- Measurable defined characteristic
- Indicator of processes or responses to an intervention
- Numerical or categorical outcome measure
- **Based on in-vivo medical imaging**

The role of AI in producing imaging biomarkers

Examples in drug evaluation trials

- Lung emphysema secondary to α_1 -antitrypsin deficiency
- Early treatment of patients with arthralgia suspected of developing rheumatoid arthritis

Different Routes to Produce an Imaging Biomarker

Classical versus Deep Learning

Classical Route: Lung CT Densitometry

Pulmonary emphysema is defined in pathological terms:

Permanently enlarged distal airspaces and destruction of their walls¹

Direct way of measuring emphysema: quantification of tissue density

X-ray absorption \equiv physical density

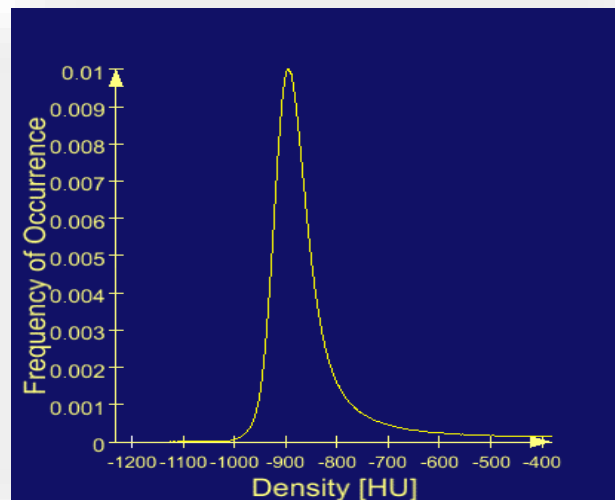

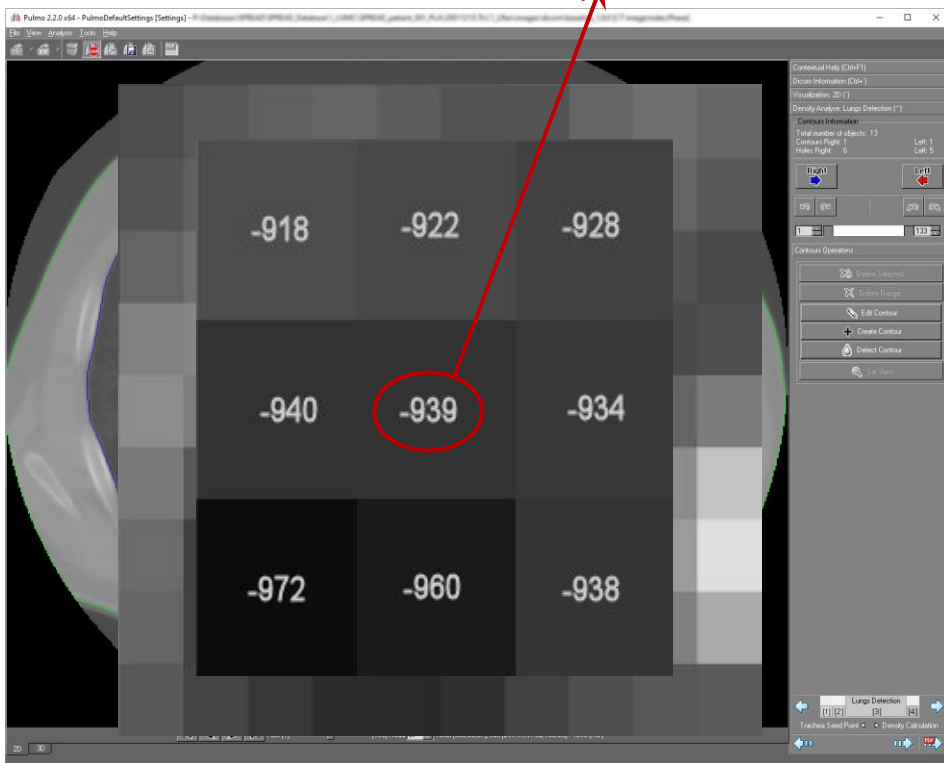

Only in the lungs: 3D imaging data from Computed Tomography

Lung CT = Densitometry

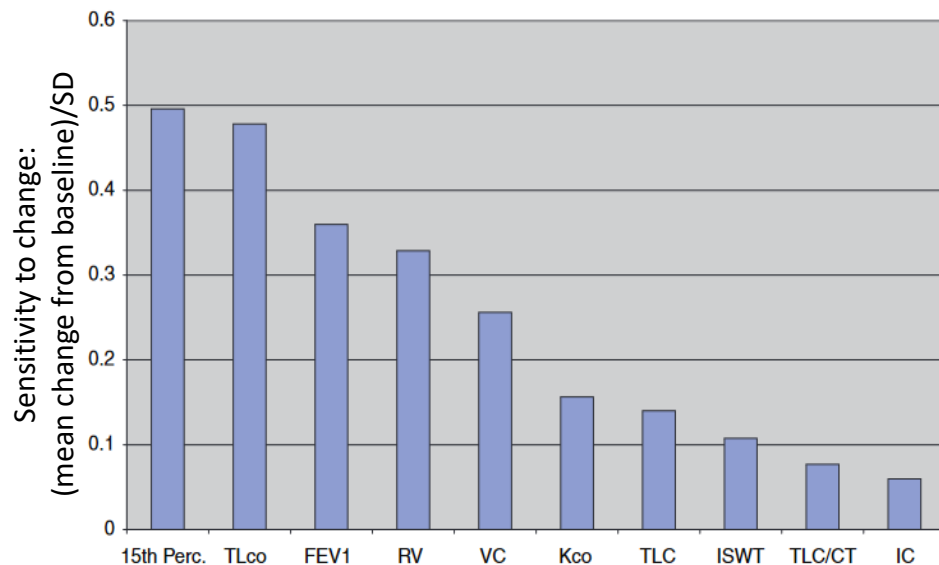

Hounsfield Unit (HU) + 1000 \approx density in gram/liter

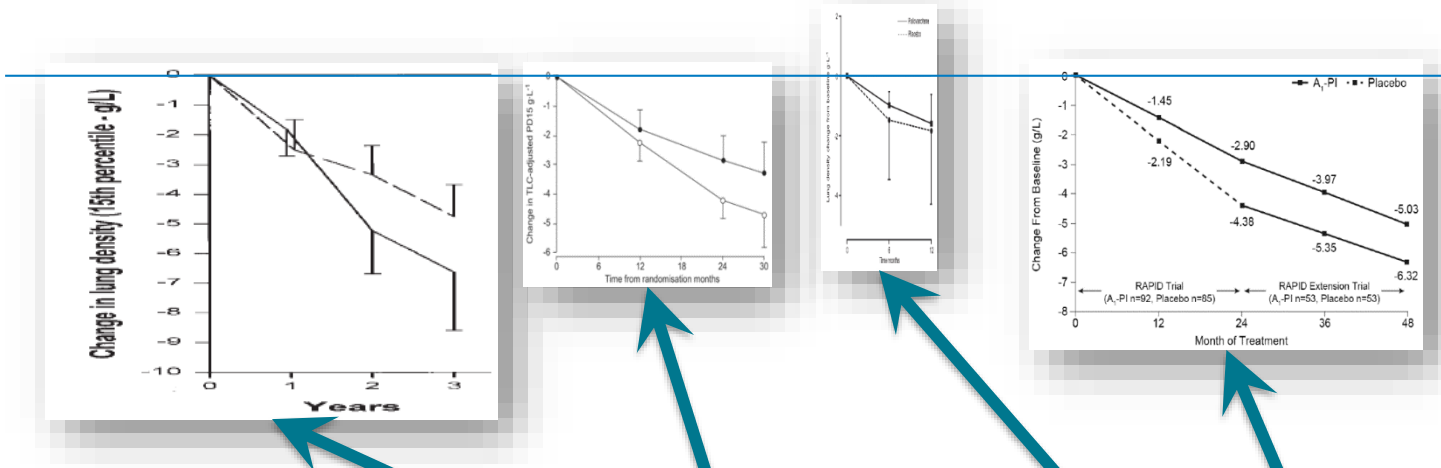

From image processing we obtain:

- Lung Volume (V)
- 15th percentile density

Classical Route: Lung CT Densitometry to Quantify Emphysema

Lung Densitometry in Drug Evaluation Trials on Emphysema Secondary to α 1-Antitrypsin Deficiency

Annual Tissue Loss (g/L/year)

	DD Study ¹ 1999 (n=27/27)	EXACTLE ² 2009 (n=39/38)	Combined ³ 2010 (n=59/60)	REPAIR ⁴ 2012 (n=133/129)	RAPID ⁵ 2015 (n=87/84)
Placebo	-2.6	-2.2	-2.7	-1.8	-2.2
Active	-1.5	-1.4	-1.7	-1.6*	-1.5

Putting Things into Perspective

Natural progression of AATD emphysema

- Each liter of lung tissue loses 2 gram (HU) per year

Treatment effect of AAT augmentation therapy

- Of each liter of lung tissue 1 gram (HU) is preserved each year

Tolerance levels for CT number accuracy in clinical practice¹:

- ± 5 HU (water)
- ± 10 HU (other material)

To correct this, internal recalibration during image analysis

Shift:

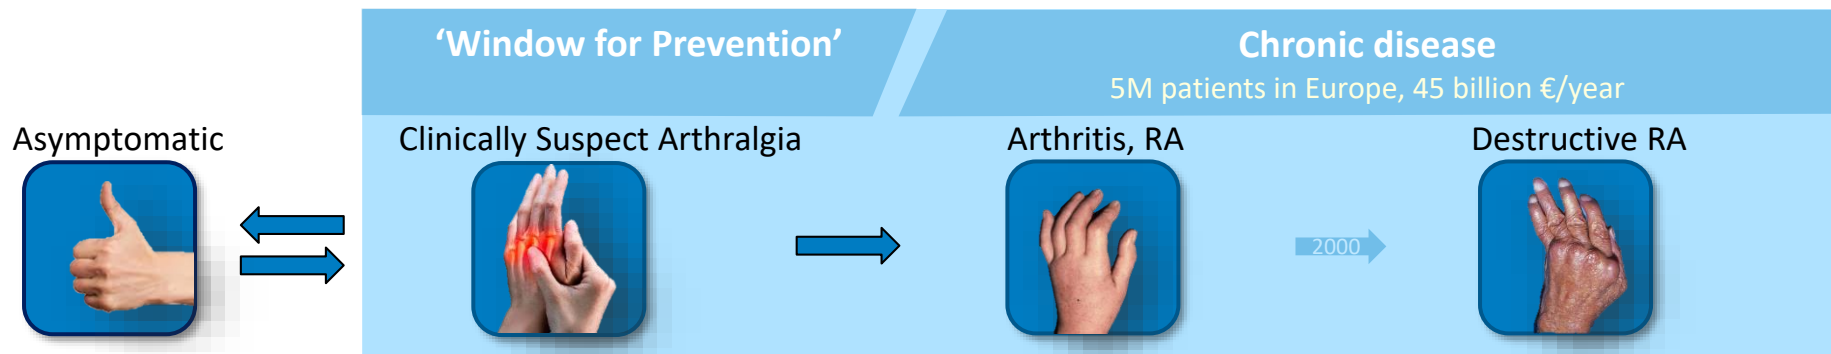

Different Routes to Produce an Imaging Biomarker

Classical versus *Deep Learning*

Rheumatoid arthritis (RA) is the most common autoimmune diseases

TREAT EARLIER Trial

Early, preventive treatment in Clinically Suspect Arthralgia (CSA) patients:

- Placebo (n=117)
- Single intramuscular glucocorticoid-injection and a one-year course of oral methotrexate (n=119)

Location		High resolution plane (T1 fat-suppressed + contrast)	# scans
Wrist	A	COR	805
	B	TRA	805
MCP	C	COR	805
	D	TRA	805
Foot (MTP)	E	COR	792
	F	TRA	787

- Four time points (BL, 4, 12 and 24 months)
- Visually scored by the RAMRIS system, by clinical experts

Inflammatory Lesions in Rheumatoid Arthritis (RA)

According to the RAMRIS system:

- Tenosynovitis

Inflammation of tendon sheaths

- | | |
|---|---|
| 0 | No tenosynovitis |
| 1 | <1.5mm tenosynovial contrast enhancement |
| 2 | ≥1.5mm but <3mm tenosynovial contrast enhancement |
| 3 | ≥3mm tenosynovial contrast enhancement |

- Synovitis

Inflammation of synovial joint-space

- | | |
|---|---|
| 0 | normal |
| 1 | mild (up to 1/3 of presumed maximum area) |
| 2 | moderate (up to 2/3 of presumed maximum area) |
| 3 | severe (>2/3 of presumed maximum) |

Inflammatory Lesions in RA

- Bone marrow edema (BME)
A.k.a. osteitis (bone inflammation)

0	no BME
1	1 – 33% of bone with osteitis
2	34 – 66% of bone with osteitis
3	67 – 100% of bone with osteitis

- Erosions
Bone loss, with cortical break

0	no erosion
1	1 – 10% of bone volume eroded
2	11 – 20% of bone volume eroded
3	21 – 30% of bone volume eroded
...	...
10	91 – 100% of bone volume eroded

Can AI Help?

A. In assessing severity of arthritis?

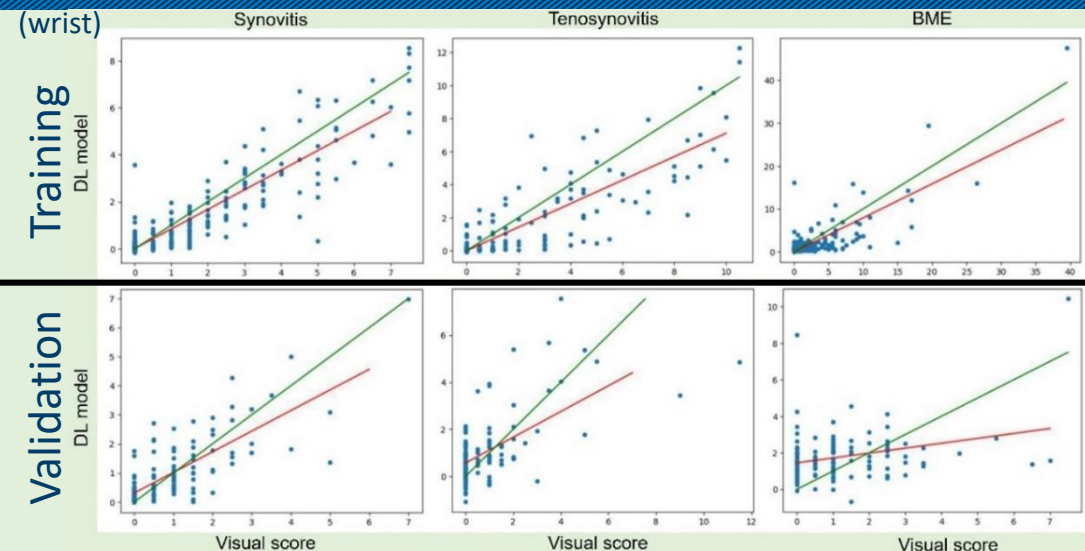

- By simulation visual scoring (RAMRIS)

- Training set: 727 clinically suspect arthralgia (CSA); 1247 early onset arthritis; and 174 healthy controls
- Validation set: 127 CSA patients from the TREAT-EARLIER trial

Simulating Visual Scoring – Results

Score (from wrist, MCP and MTP)	Corr. (SD)
Total inflammation (rough reference, 2 observers)	0.88 (± 0.03)
Synovitis	0.86 (± 0.05)
Tenosynovitis	0.83 (± 0.06)
BME	0.65 (± 0.11)
Total inflammation (rough reference, 2 observers)	0.73 (± 0.03)
Synovitis	0.74 (± 0.02)
Tenosynovitis	0.61 (± 0.06)
BME	0.12 (± 0.04)

Training

Validation

Heatmaps for tendon groups with RAMRIS scores higher than one:

Based on DL model, the heatmaps highlight the regions for:

Can AI Help?

A. In assessing severity of arthritis?

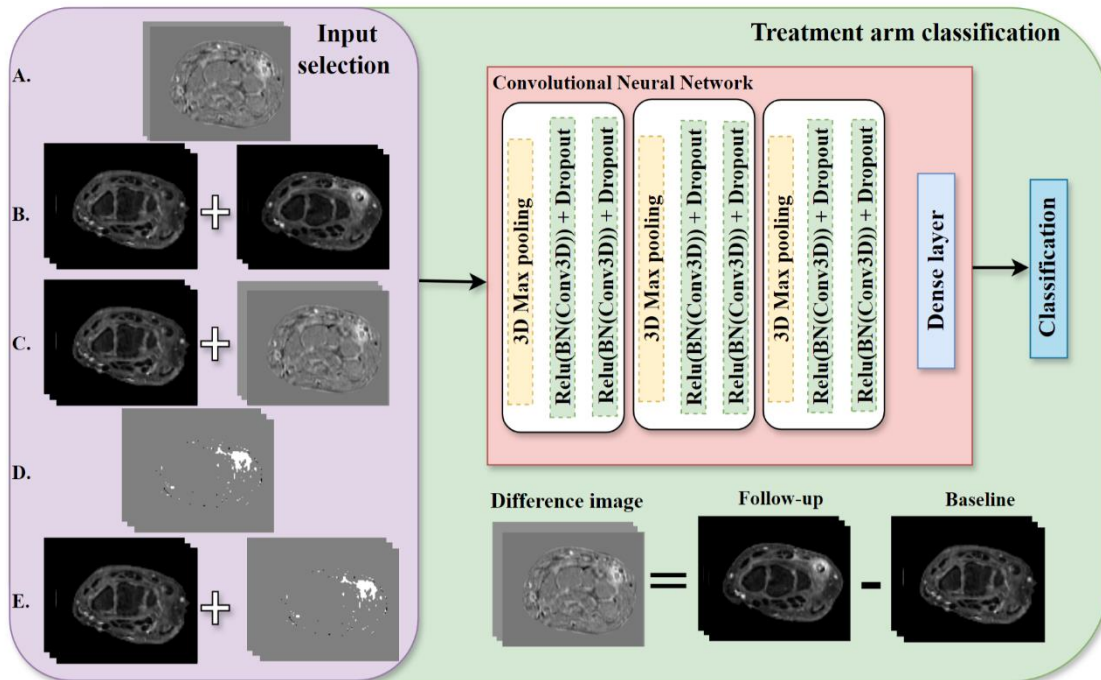

- By simulation visual scoring (RAMRIS)

B. Localizing treatment effects?

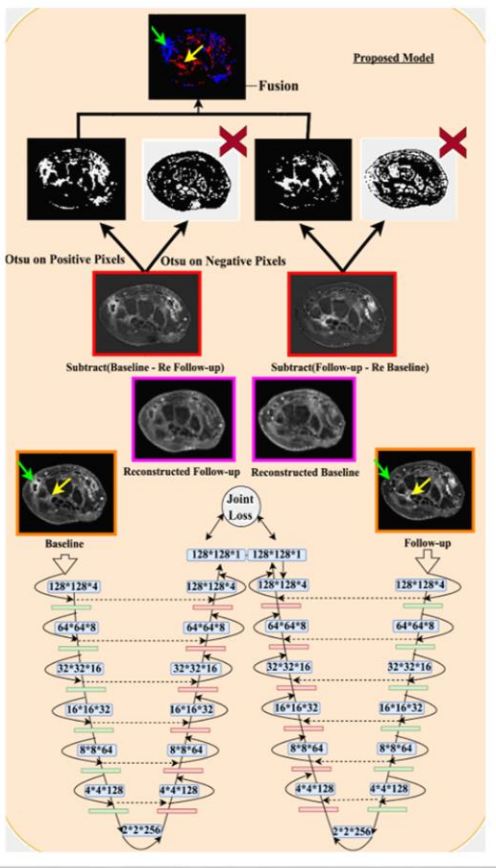

C. Predicting treatment response?

- By classifying MRI scans into treatment arm: active or placebo
- The learned features then contain the treatment effects, to be displayed in saliency maps

10-fold cross-validation
AUC: 0.80

Localizing Possible Treatment Effects: Change Maps

Assumptions:

- Predictable changes are coming from the (non-calibrated) MRI scanner
- Unpredictable changes are relevant changes

intensity
■ increase
■ decrease

Classification, Explanation Methods

Focused on change maps of the wrist (since segmentations are available)

1. By Input Blocking

- At a **voxel** level: by square masks at each position in the image

- At **anatomical** level (tenosynovium, synovium, bones, tendons, vessels, skin, remaining tissue)

2. By Class Activation Maps (CAMs)

Interpretation of Blocking Effects

Original change map:

Trained CNN

Initial classification:

TP FP TN FN

Masked change map:

Trained CNN

Classification after masking:

TP FN FP TN TN FP FN TP

Confidence change in target class (P/N):

Inconclusive/not helping	Relevant	Irrelevant	Misleading
--------------------------	----------	------------	------------

Results: Voxel-based Blocking and CAMs

	Image data			Saliency maps	
	Baseline	Follow-up	Change map	Δ Confidence	CAM
Example 1 (TN): Label = PLA Output = PLA					
Example 2 (TP): Label = TRT Output = TRT					
Example 3 (FN): Label = TRT Output = PLA					
Example 4 (FP): Label = PLA Output = TRT					

Misleading
 Irrelevant
 Relevant

Anatomical Level Masking

(%)	Synovium	Tenosynovium	Bone	Skin	Vessel	Tendon
Irrelevant	74.05	63.24	77.84	72.97	75.14	80.00
Relevant	6.49	17.30	2.70	7.57	5.41	0.54
Misleading	1.08	1.08	0.00	2.16	0.54	0.00
Not helping	18.38	18.38	19.46	17.30	18.92	19.46

Can AI Help?

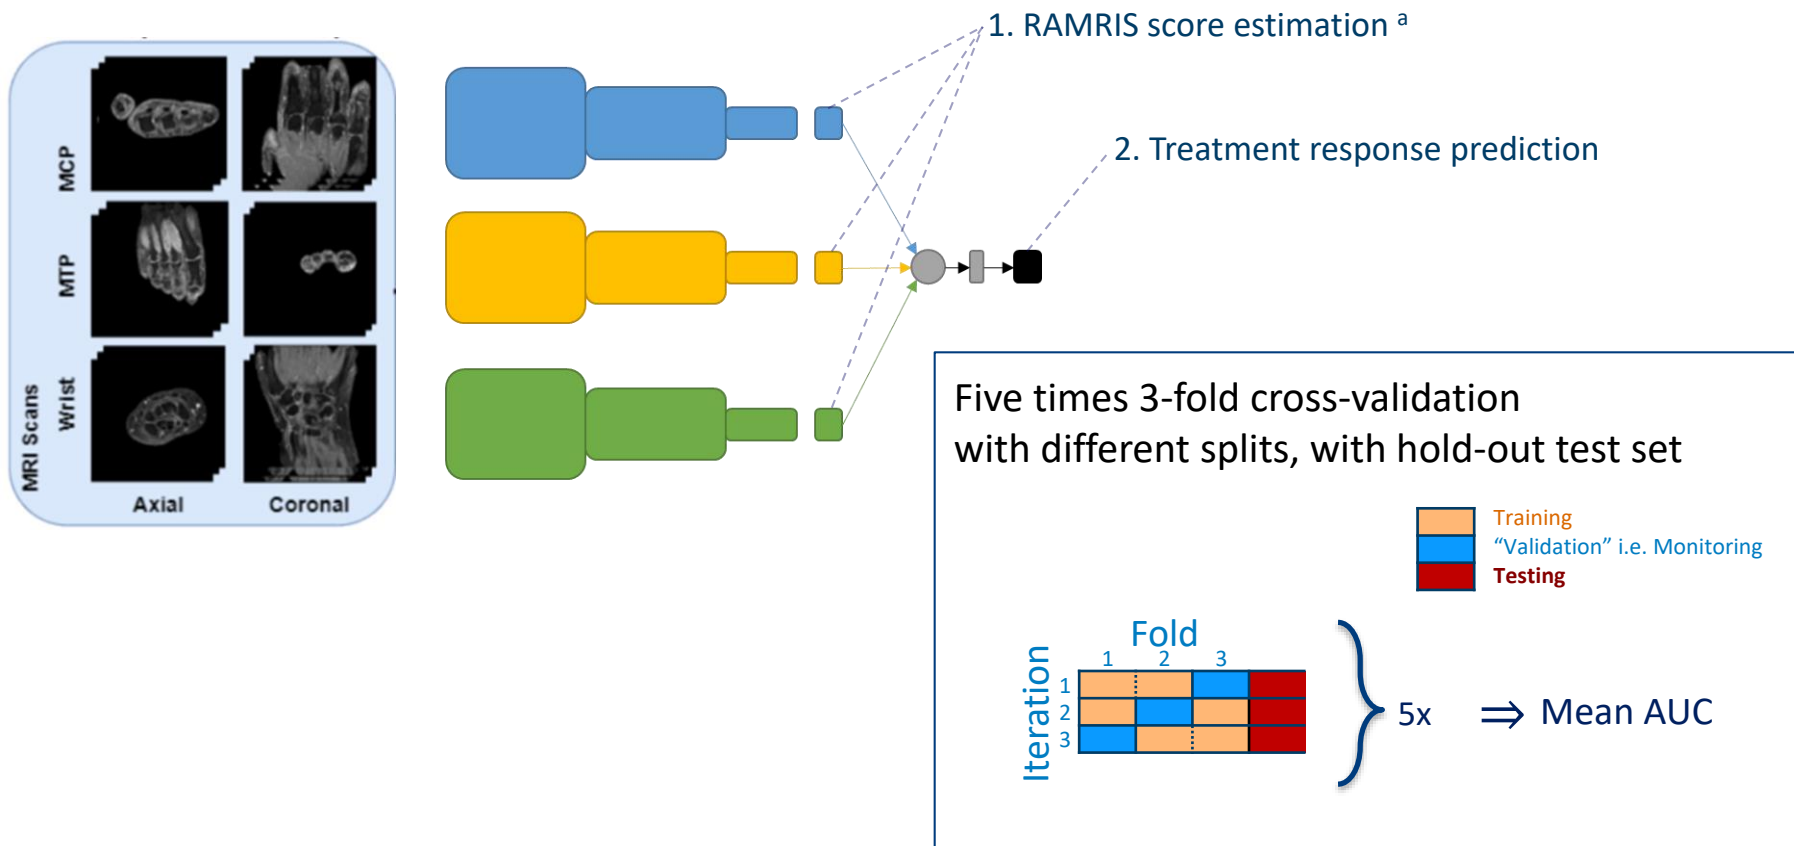

- A. In assessing severity of arthritis?
 - By simulation visual scoring (RAMRIS)
- B. Localizing treatment effects?
- C. **Predicting treatment response?**
 - Facilitate patient selection
 - Prevent overtreatment

Definition of treatment response:

Decrease in visual score of inflammation > 3 points (RAMRIS)
≡ smallest detectable change in visual score, by two observers

Treatment Response Prediction: Two-step Approach

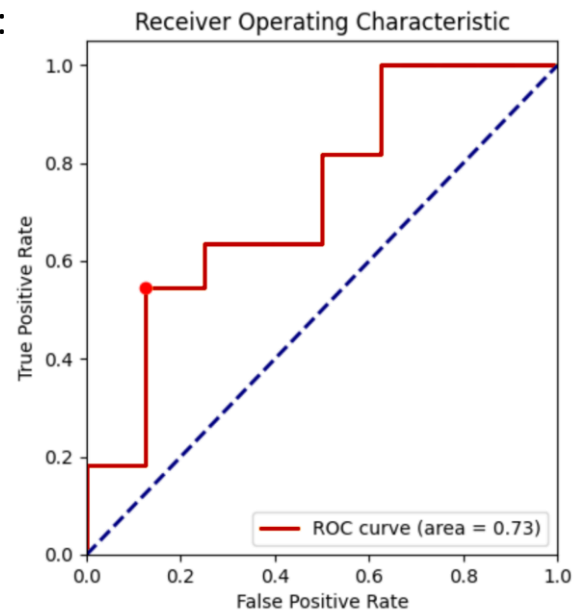

Treatment Response Prediction: Results

AUC: 72% \pm 7.83

Test characteristics (n=27):

- Positive predictive value: 65 %
- Negative predictive value: 79 %
- Sensitivity: 53 %
- Specificity: 86 %

5th Experiment:

Conclusions on the Role of AI

AI can help in

- Assessing severity of arthritis
- Localizing treatment effects
- Predicting treatment response, to facilitate patient selection

Classical imaging biomarker	Deep learning based biomarker
Easily explainable	Explainable AI: work in progress
Manual correction possible	Work in progress
Quality control is relatively simple	Complex
Imaging biomarkers are interpretable	Interpretation through saliency maps
Restricted to chosen features	Possibility to discover new features
Based on prior knowledge	Hypothesis generation
Both need stringent quality control of image acquisition
