ESA UNCLASSIFIED – For ESA Official Use Only

Some context: CH₄ emissions over offshore sources

- CH₄ emission mitigation from anthropogenic sources is key to curb global warming

- Oil and Gas (O&G) industry:

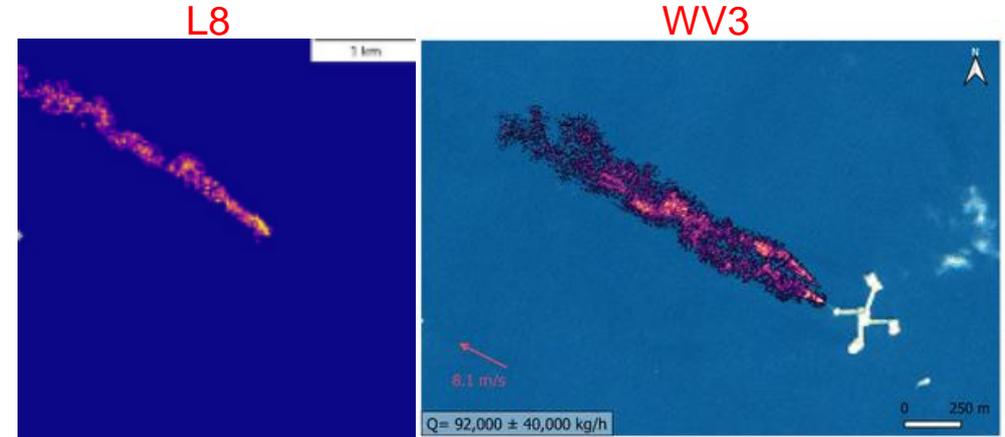

- ~35% of anthropogenic sources
- Remote sensing: point-sources (easier to detect)
- Observations -> mitigation strategy

- Offshore O&G:

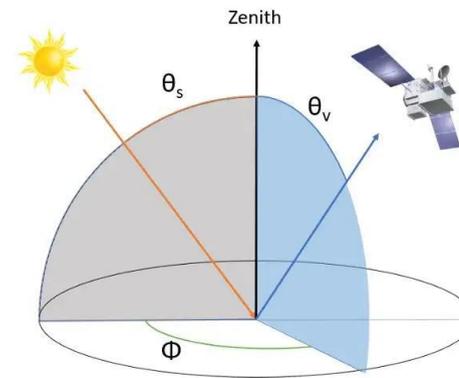

- ~30% of O&G production
- Issue: typical low radiance (Rad) of water
- But... sunglint effect!
- Probability to detect with satellite-based sensors?
- We will study this aspect for...

EnMAP (~PRISMA) and **EMIT**

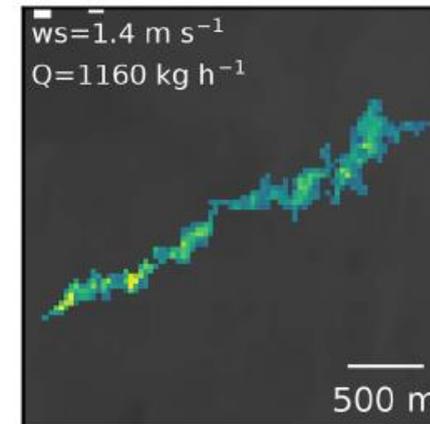

(Public data + instrumental for point-sources)

Irakulis-Loitxate et al. (2022)

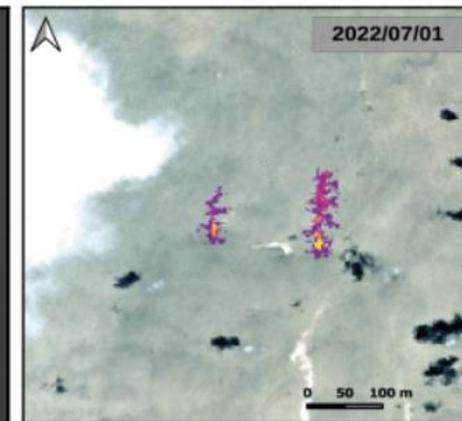

GHGSat

MacLean et al. (2023)

EnMAP

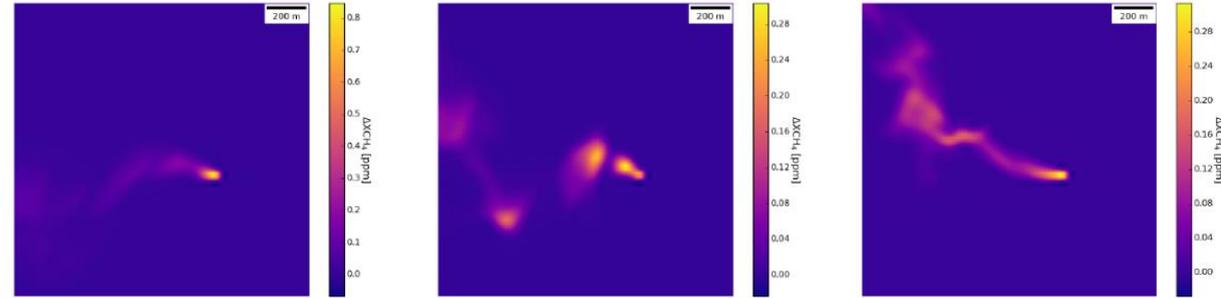

Roger et al. (2024a)

How do we determine the chances to detect?

- Chances to detect -> Detection Limit (DL) concept:

- Flux rate (Q , t/h) value in which we detect 50% of the plumes
- Rad is the main driver for detection
- We want to obtain Rad vs DL curves

Gorroño et al. (2023)

- L1 data: 67-EnMAP and 27-EMIT acquisitions

- We integrate simulated plumes (x60) into the radiance data

- The matched-filter is used to obtain CH₄ retrievals

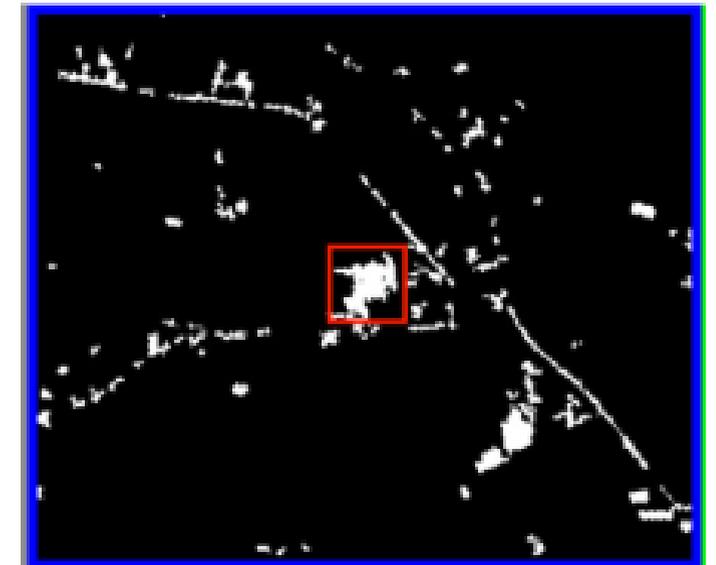

- For each plume and acquisition, we find the minimum Q for detection

- $DL = Q$ at which we detect 50% of the plumes ($\sim \text{mean}(Q)$)

- $\text{err}(DL) = 1\text{-std}$ of the distribution

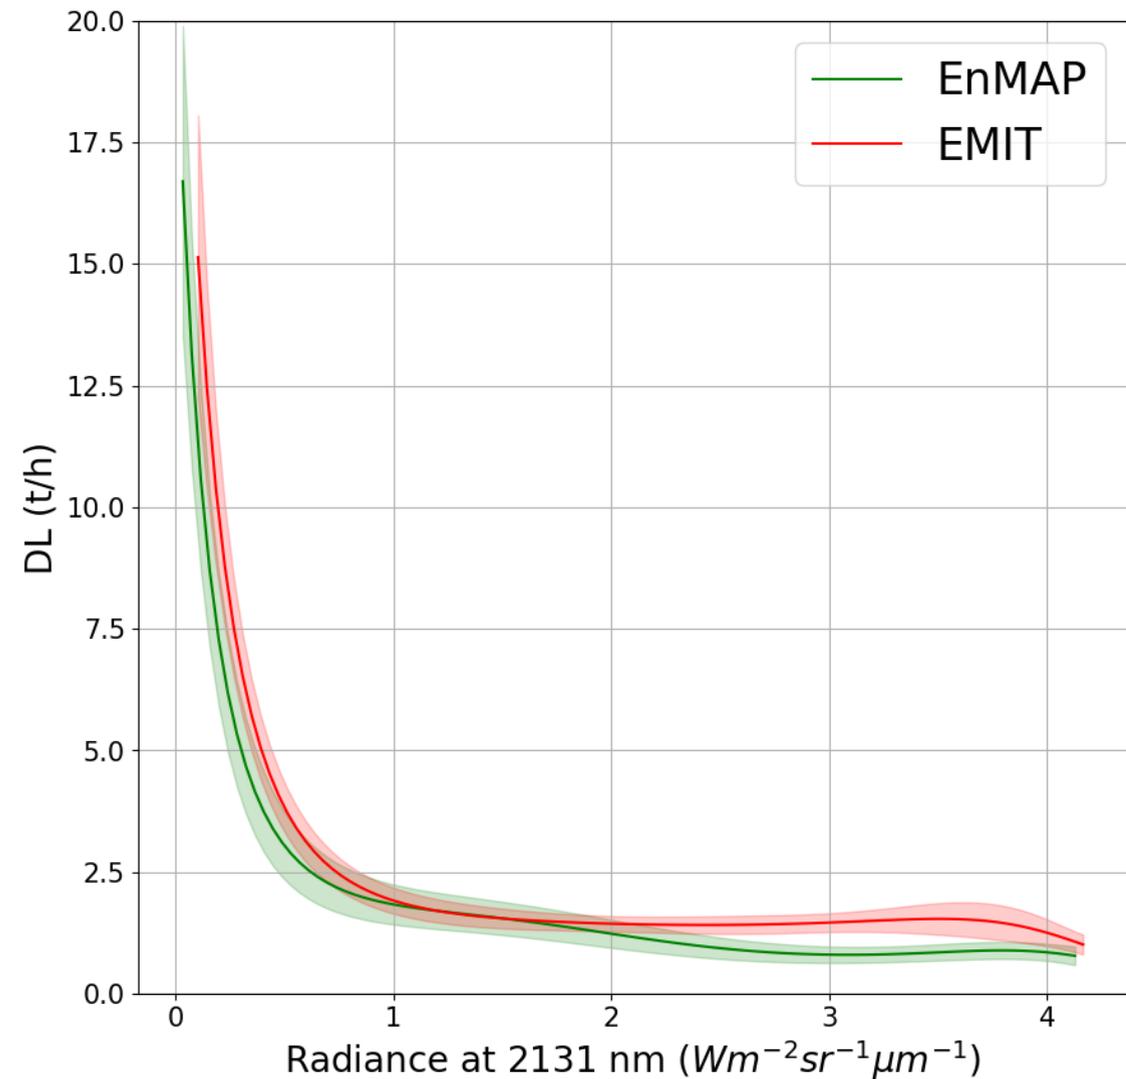

Automatic emission detection algorithm

(test for emission detection)

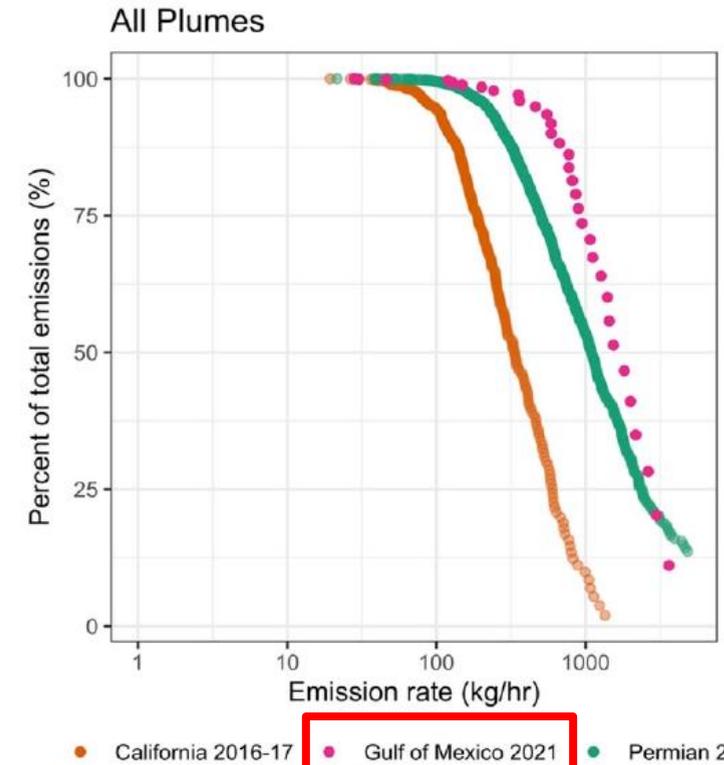

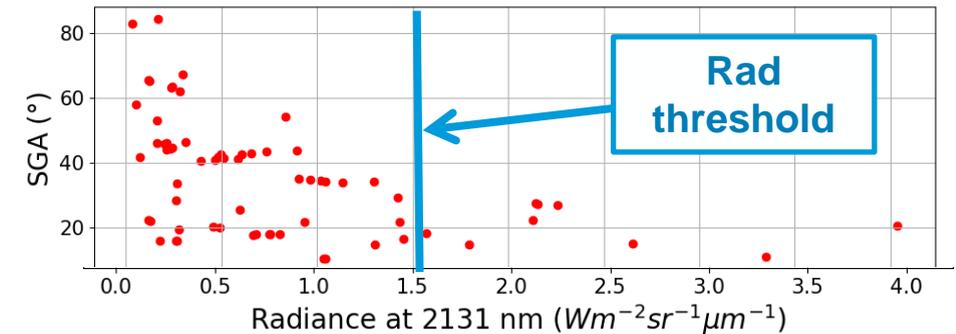

Roger et al. (2024b)

- EMIT curve is more unstable:
 - Lower number of acquisitions (*we can improve this*)
- $DL(EnMAP) < DL(EMIT)$
- Now, questions:
 - How much impact has the sunglint in these results?
 - Can we see typical offshore emissions?

Sunglint importance - Analysis made on EnMAP data

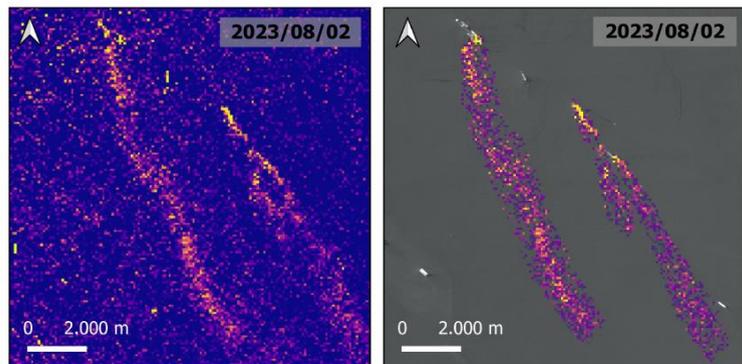

- Scattering Glint Angle (SGA):
 - SGA = Angular distance to the sunglint configuration
 - We manually separate \downarrow Rad from \uparrow Rad (*Rad threshold* $\sim 1.5 \text{ Wm}^{-2}\text{sr}^{-1}\mu\text{m}^{-1}$)
 - \uparrow Rad only for SGA $< 30^\circ$:
 - **\uparrow Rad only with sunglint!!**
 - Just a few points: **+ difficult to find close-to-sunglint data**
- Typical offshore plumes:
 - At *Rad threshold*, DL = 1.5 t/h.
 - Airborne campaigning in the GoM (Ayasse et al., (2022))
 - > 100 plumes detected
 - No plume with Q > 1.5 t/h
 - **Sunglint needed for typical offshore plumes!!**

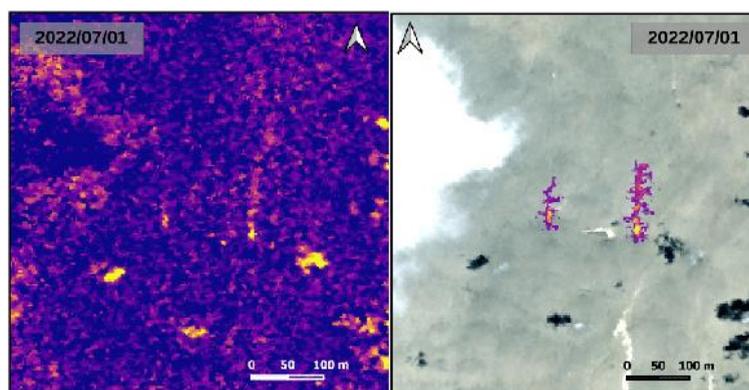

Ayasse et al. (2022)

Show cases - CH₄ emissions from offshore platforms

Conclusions

- In similar radiance conditions, EnMAP is more suitable to detect emissions than EMIT
- The sunglint effect is key to detect typical offshore emissions, but it is difficult to obtain data of this kind.
- Some offshore emissions have been collected using PRISMA, EnMAP and EMIT

Future work

- We will increase the number of acquisitions to obtain more robust results
- We will attempt to adapt the empirical results to a model using the IME quantification method (more general result)
- A manuscript will be written and submitted to a journal for publication

This work has been partly funded by the HiResCH4 project of ESA's EO Science for Society Open Call programme and partly funded in the framework of UNEP's International Methane Emissions Observatory (IMEO)
