Proglacial lakes form in front of glaciers.

Water is often trapped due to the underlying topography or by the presence of another glacier.

- As Icelandic glaciers retreat, the area of proglacial lakes has increased¹.
- The interactions between the proglacial lake and glacier will affect glacier dynamics^{2,3}.
- Iceland is experiencing the second highest rate of increase in glacial lake volume in the world⁴.

Múlajökull

Hofsjökull is the third largest ice cap in Iceland⁵.

Múlajökull is surrounded by the only known area of active drumlins⁶.

1

Glacier
mapping

Glacier terminus positions were manually delineated from Landsat optical imagery at five time periods.

2 Identify proglacial lakes

55 scenes from Landsat 5, 7 and 8.

The Normalised Difference Water Index (NDWI) was calculated using Green and near infrared bands of each satellite image.

3

Area
calculation

Area is calculated in the Google Earth Engine Script based on the number of pixels identified as water and the resolution of the image.

region of interest.

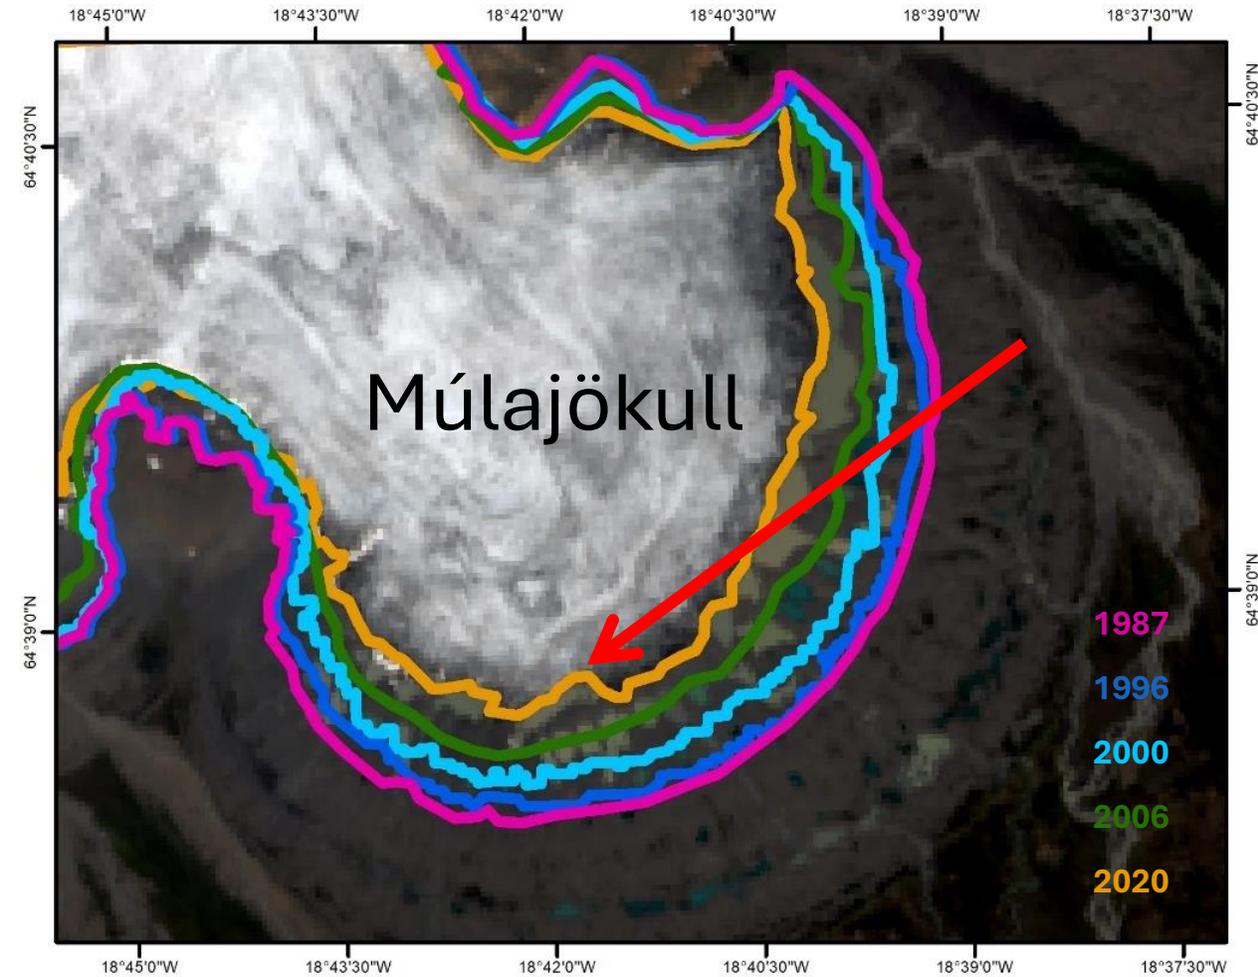

Múlajökull terminus retreat

Between 1987 and 2020 the terminus of Múlajökull retreated approximately 600 m exposing an area of 4.62 km².

Approximately 400 m of this retreat occurred after 2000.

Landsat 8 image (02/07/2020) of Múlajökull outlet glacier with manually delineated glacier terminus positions.

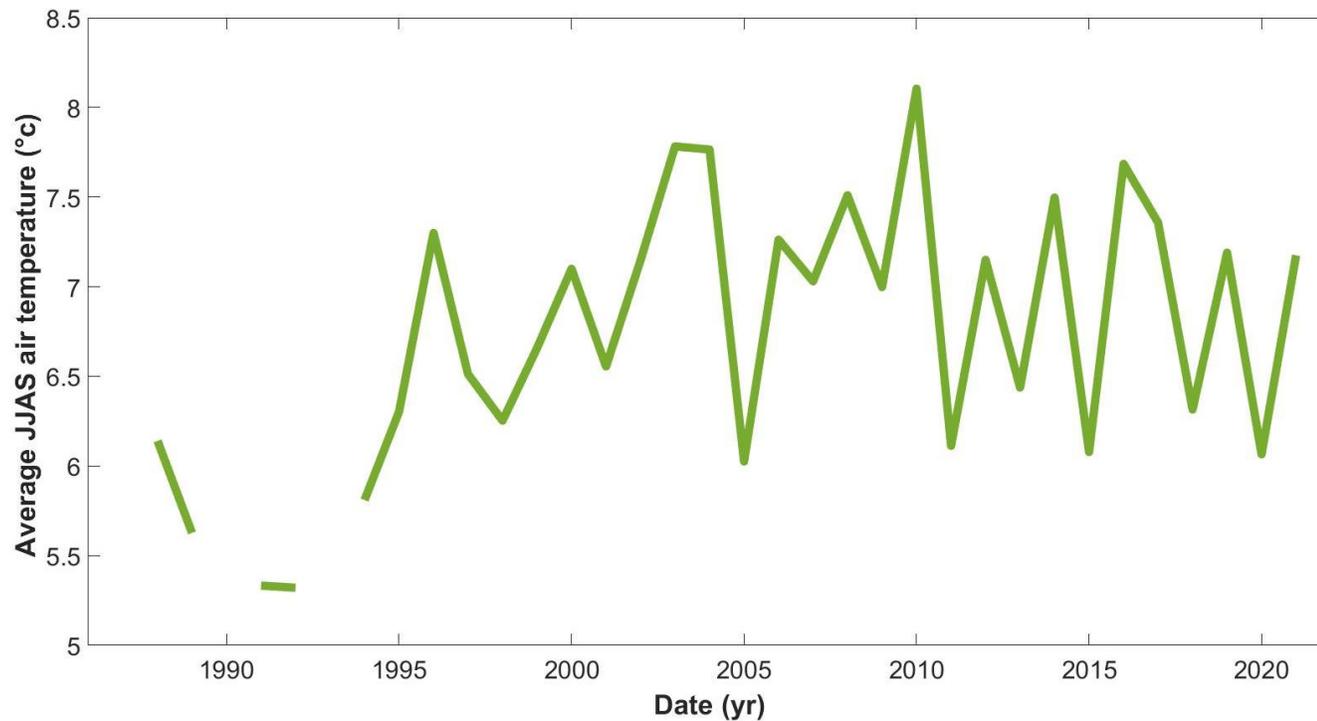

Landsat 8 image (02/07/2020) of Múlajökull outlet glacier with manually delineated glacier terminus positions.

Múlajökull terminus retreat

Terminus retreat is controlled by the underlying topography.

Greatest terminus retreat observed where direct contact with proglacial lake.

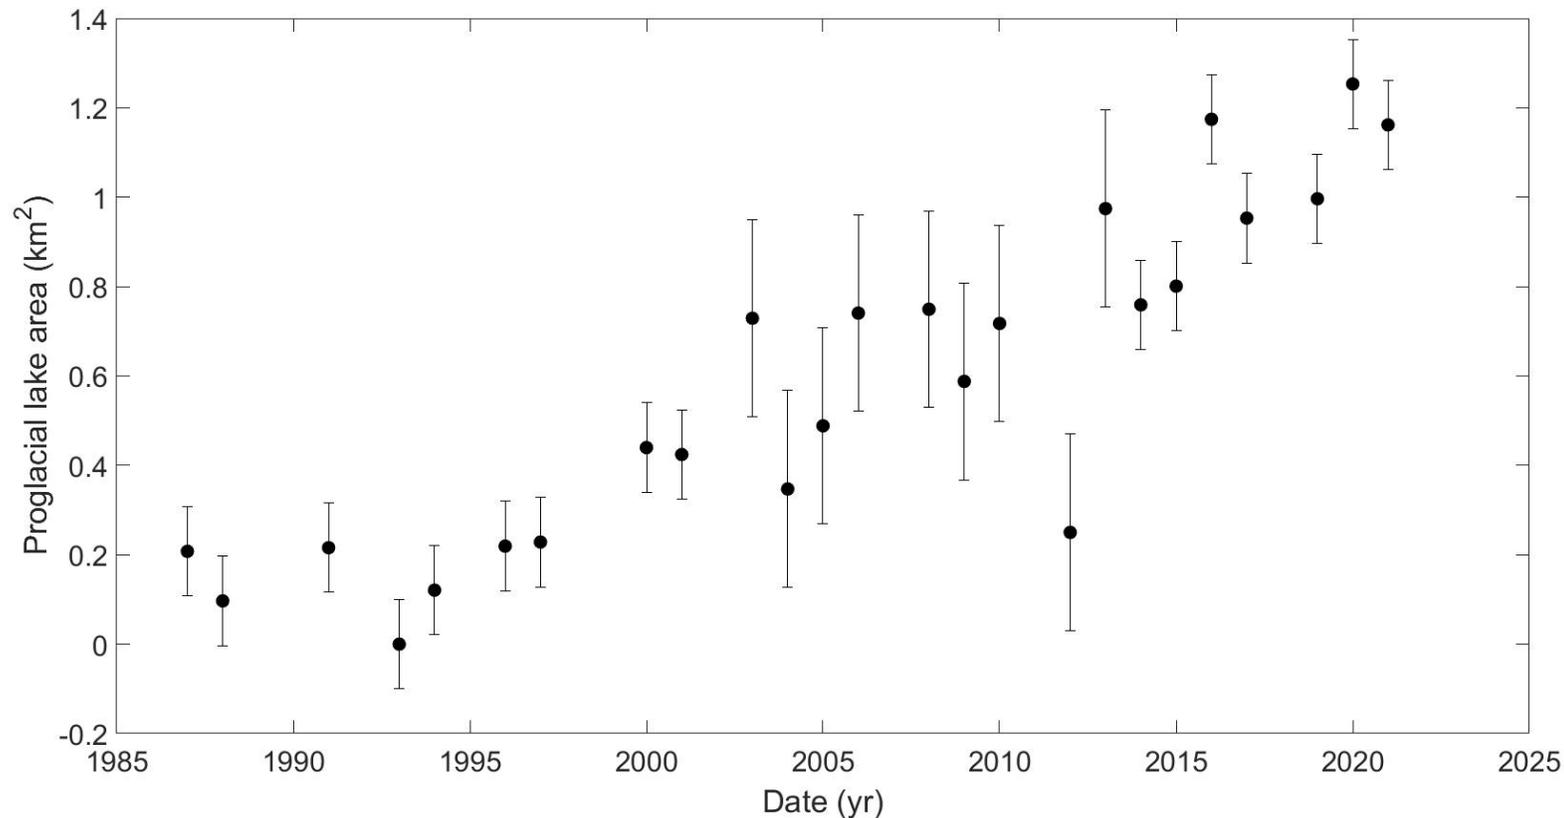

Air temperature change

Observed terminus retreat driven by increase in air temperature.

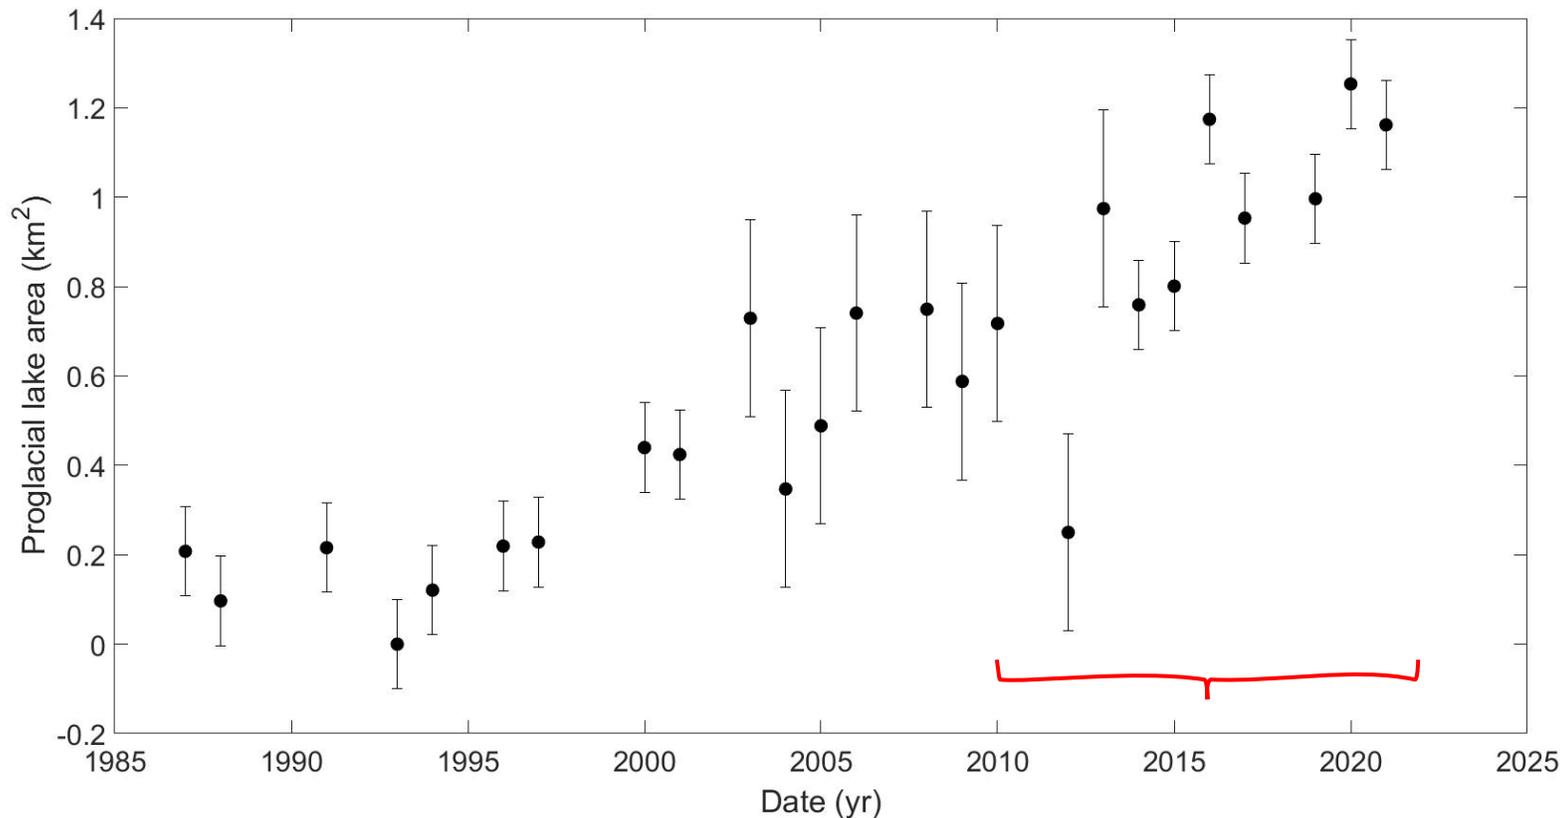

Average JJAS air temperature at Þúfuver weather station increased by 1°C.

Total area change

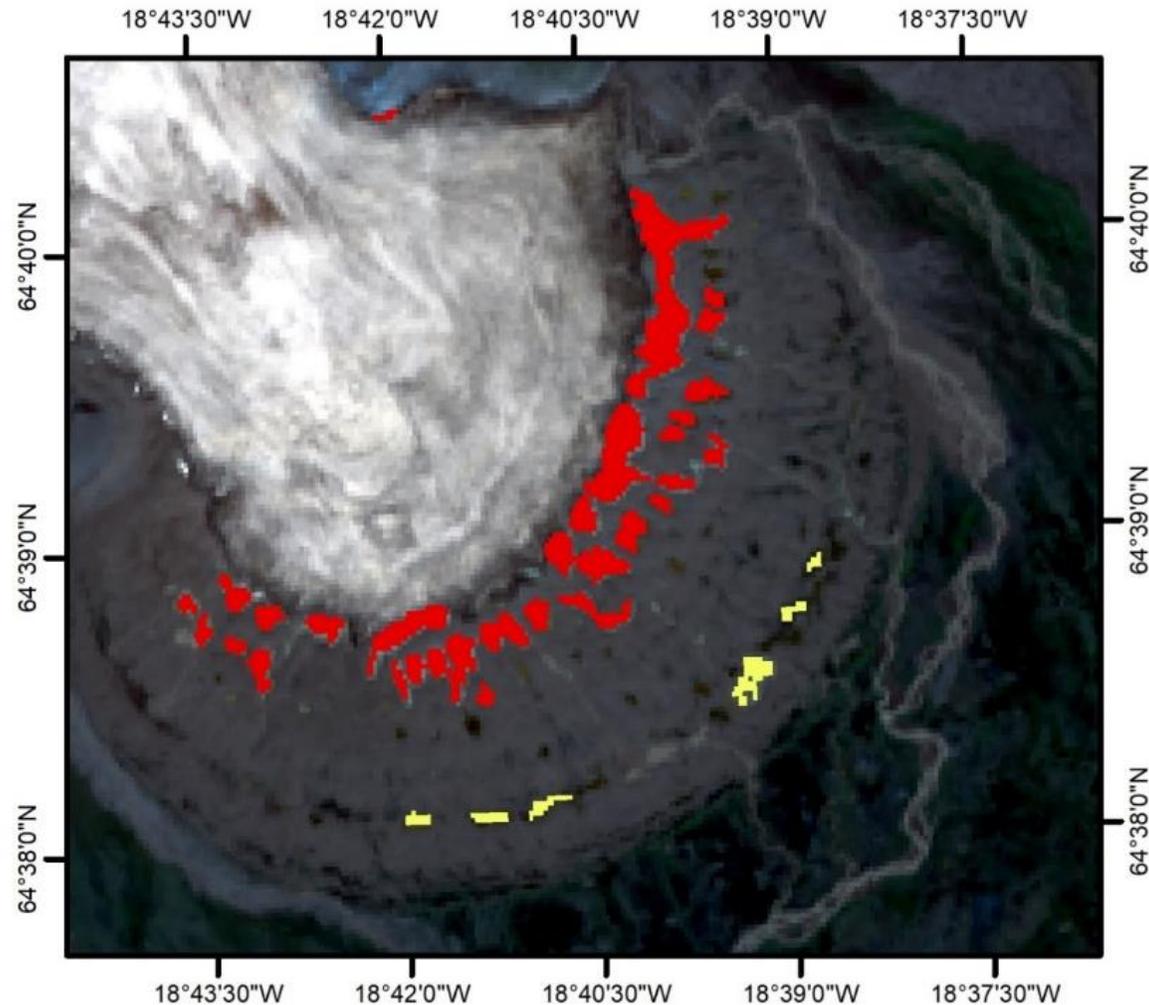

Proglacial lake area increased from 0.21 km² to 1.16 km² between 1987 and 2021.

Total area change

The greatest period of increase was between 2010 and 2021 where proglacial lake area increased from 0.72 km² to 1.16 km².

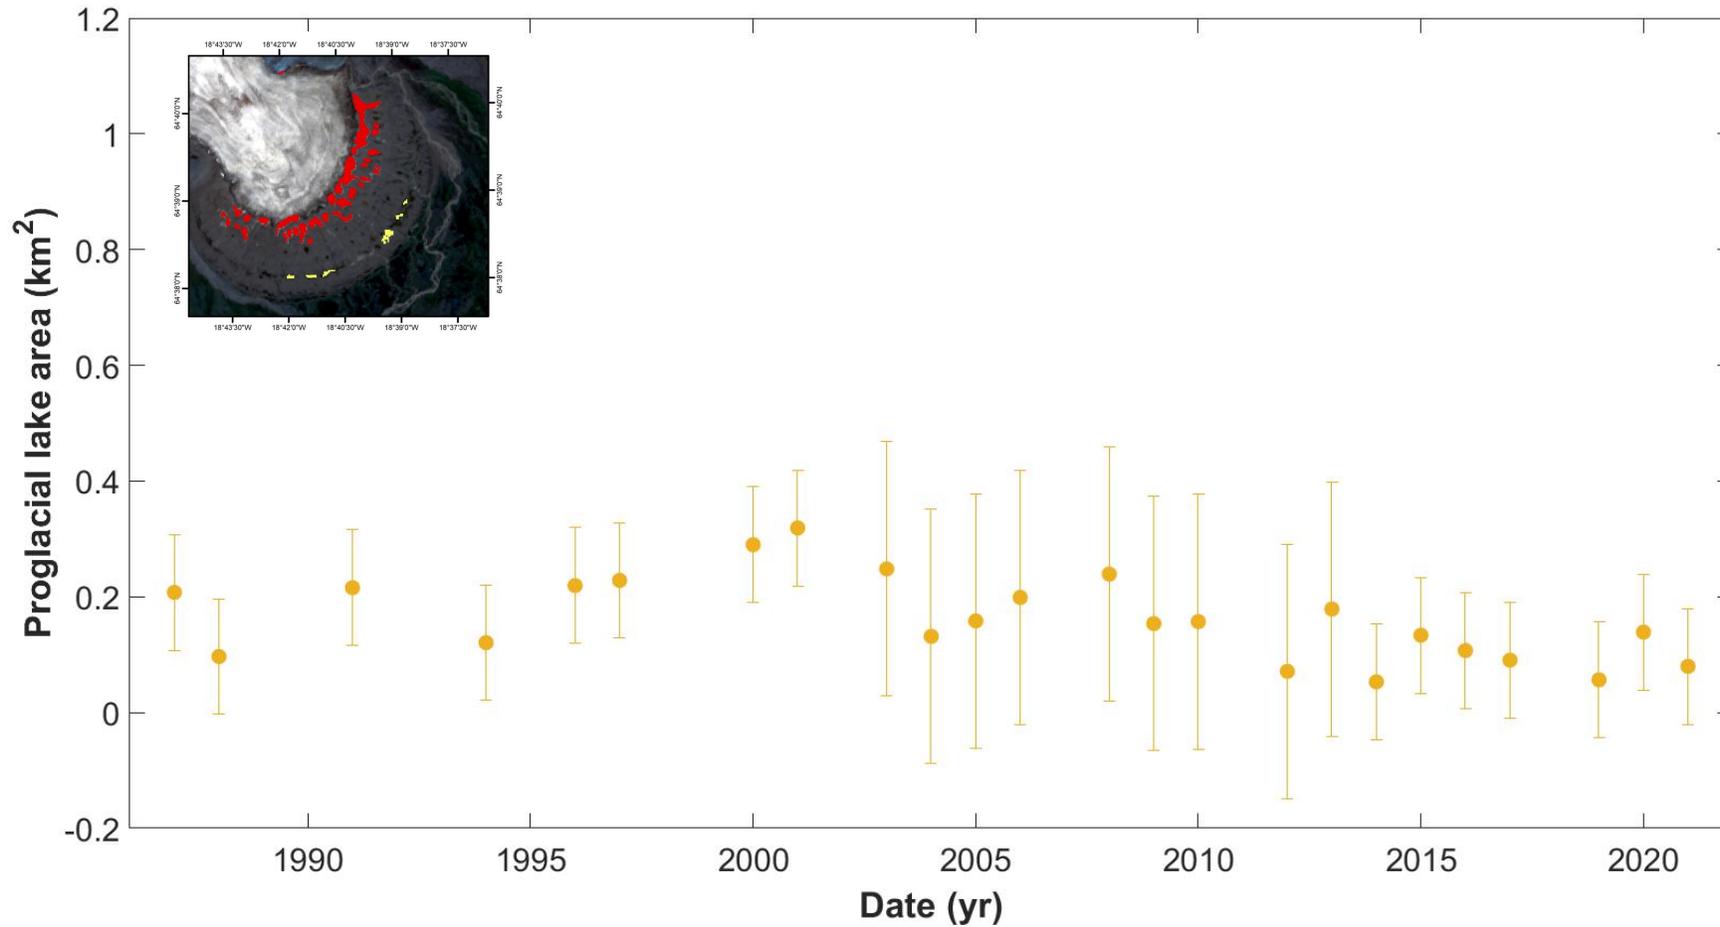

Landsat 8 image (02/07/2020) of Múlajökull outlet glacier with identified proglacial lakes.

Cause of lake area change

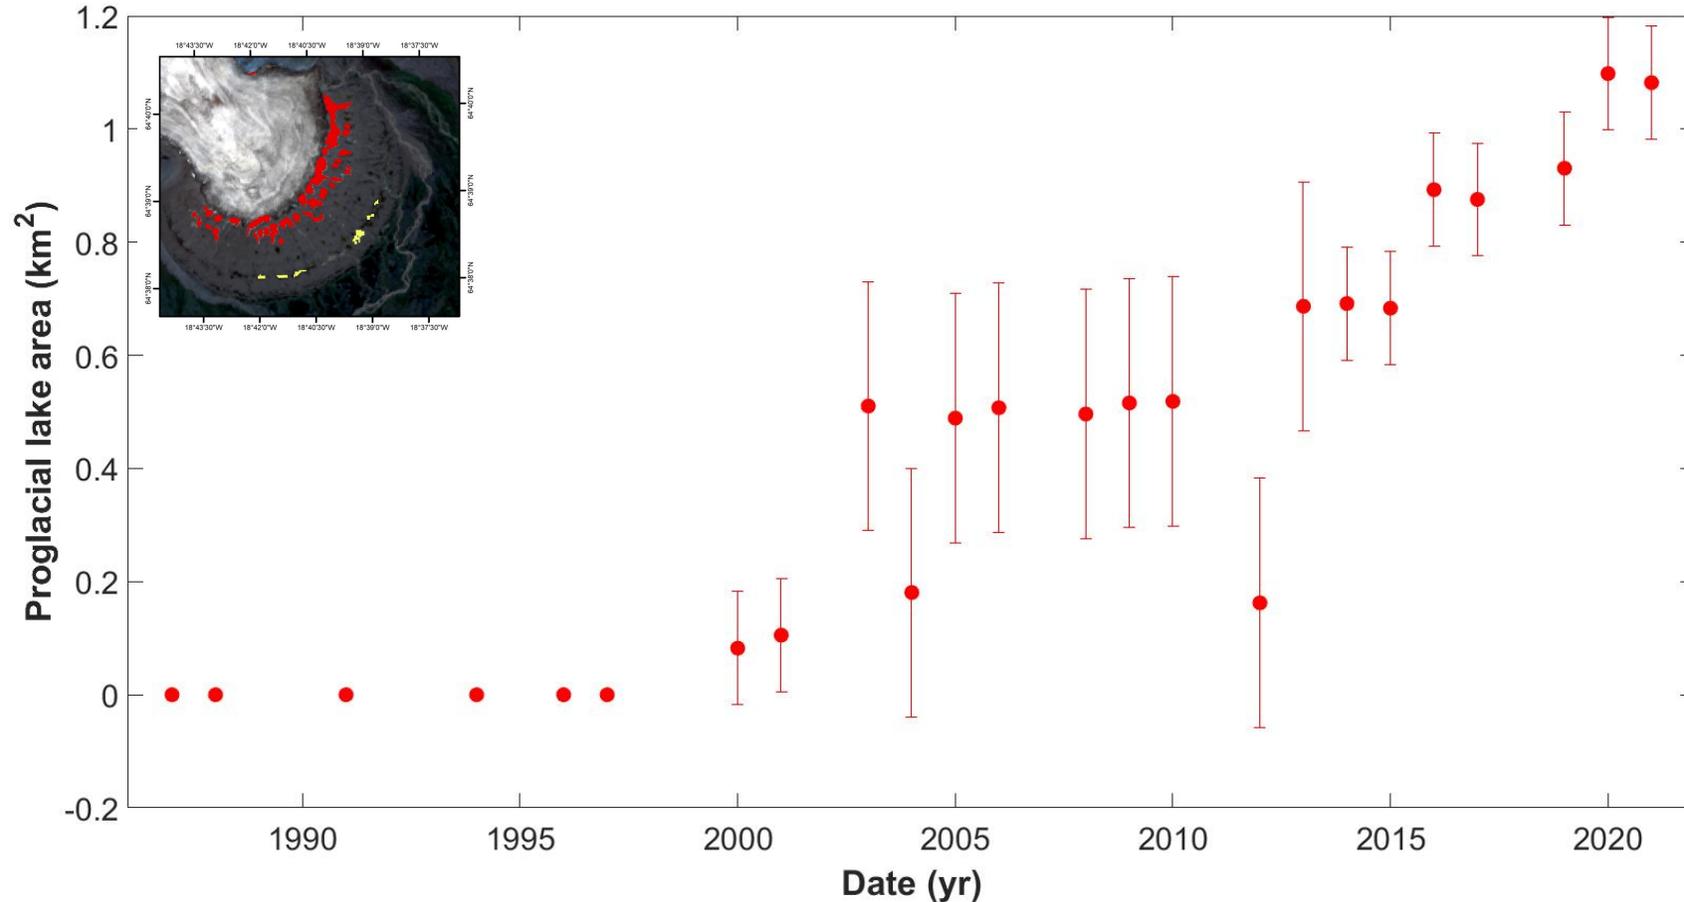

To analyse the relationship between terminus retreat and proglacial lakes the area is split into three.

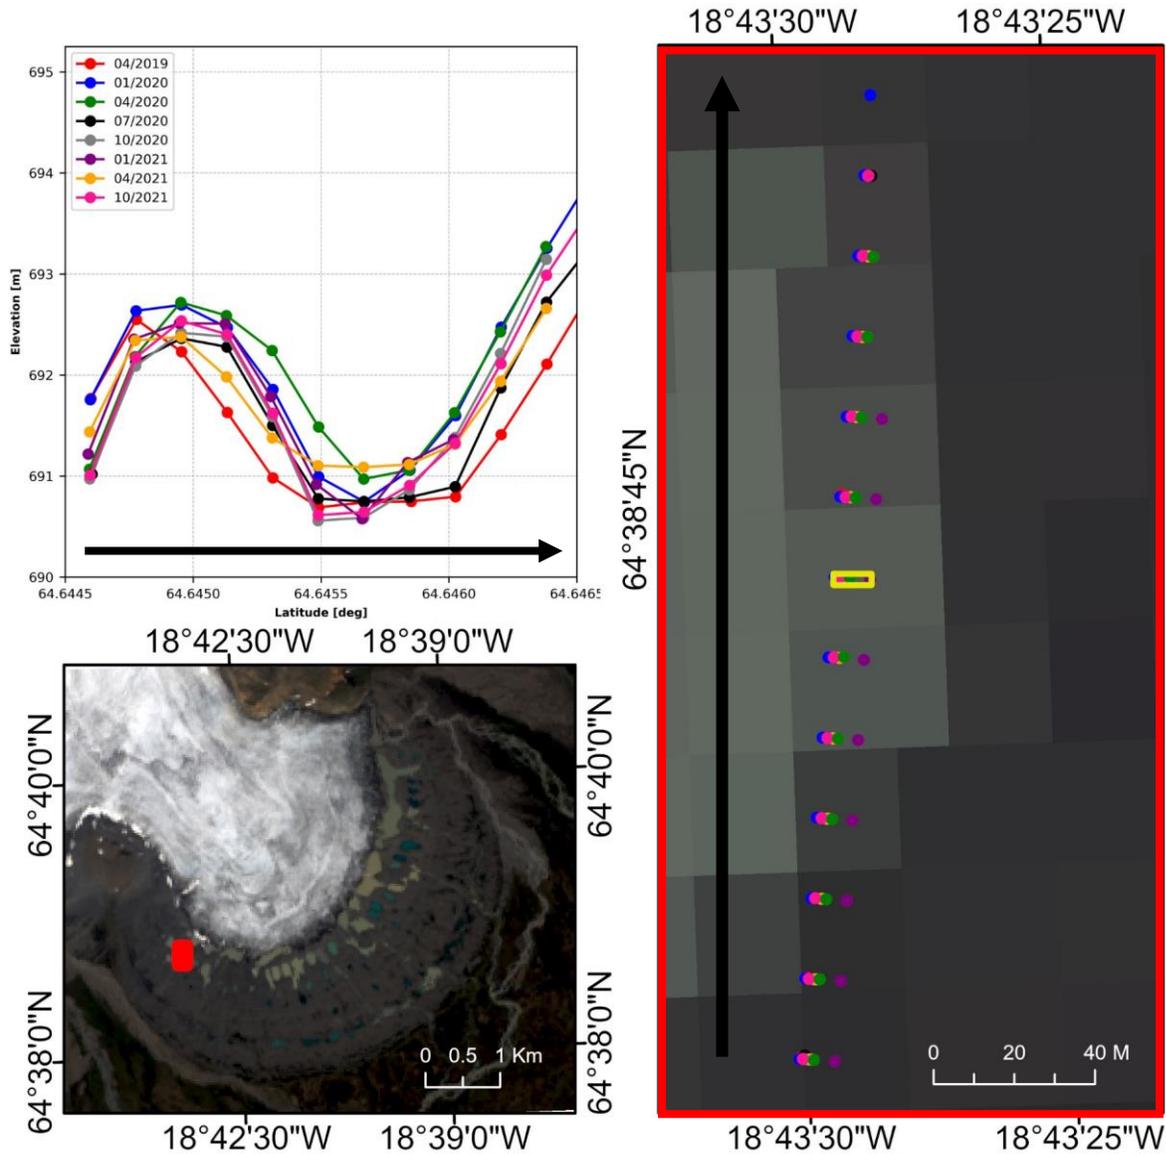

- Commonly exposed area (first identified in 1987)
- Newly exposed area (expose post 2000)
- Total (both areas)

Commonly exposed area change

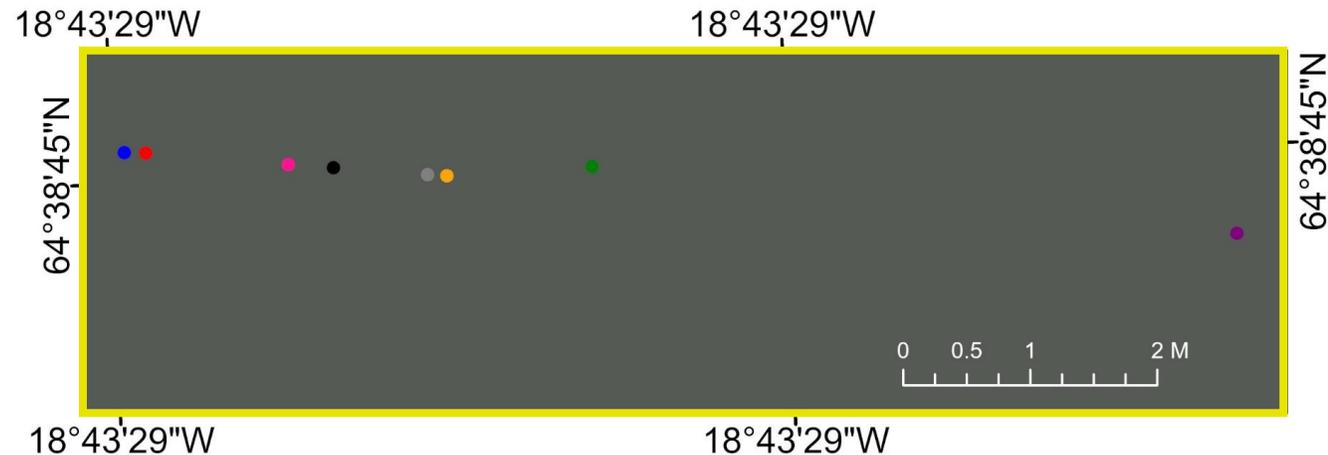

Newly exposed area change

Key points

Retreat of Múljökull coincided with a **growth in proglacial lake area**.

Most of the increase in proglacial lake area has happened **after 2000**.

A quick look at Icesat-2 tracks over proglacial lakes shows **elevation change signal** however, developing this should be the focus of future work. Co-registration of data and removal of outliers is required
