

Uncovering sleep-related barriers to motor recovery after stroke:

Behavioural, neurophysiological, and structural insights.

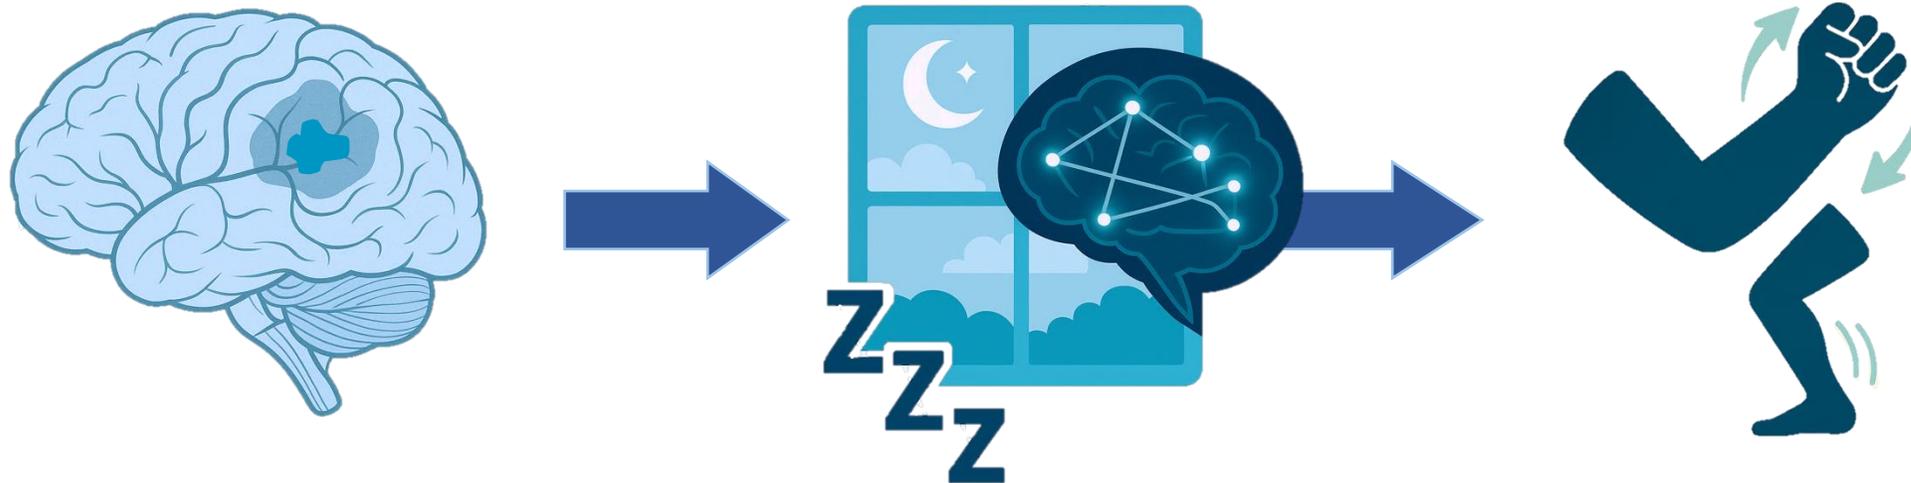

UNIVERSITY OF
OXFORD

CENTRE for
INTEGRATIVE
NEUROIMAGING

Background

- Stroke is a leading cause of worldwide disability, with over 50% of stroke survivors experiencing long-term motor impairment.
- As good outcomes after stroke are dependent on the ability of the brain to adapt and repair, it is critical we understand how neuroplasticity can be influenced shortly after stroke to maximise recovery.
- Sleep has long been thought to offer a unique window of opportunity for neuroplasticity and thus may be an important and modifiable target for post-stroke recovery

Sleep after Stroke

- Sleep disruption is commonplace after stroke
- Estimated prevalence of post-stroke insomnia has been reported to be as high as 60%

Brain Injury

Medications

Daily Routines

Mood

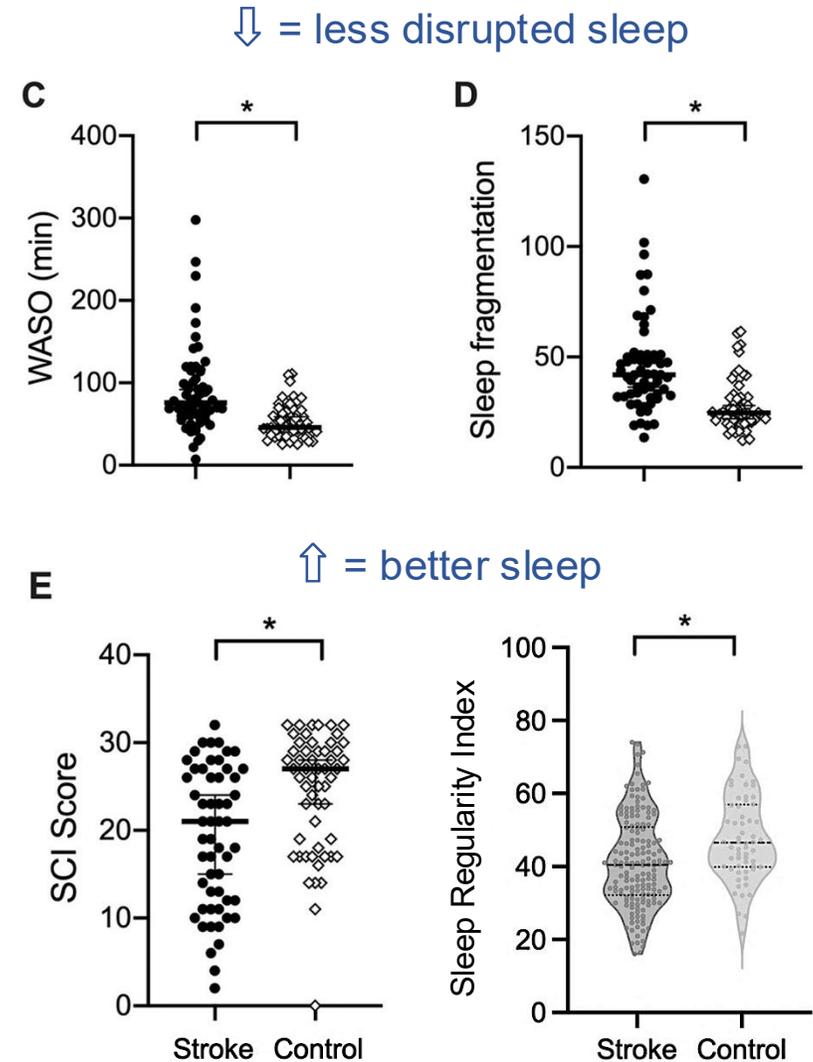

Incontinence

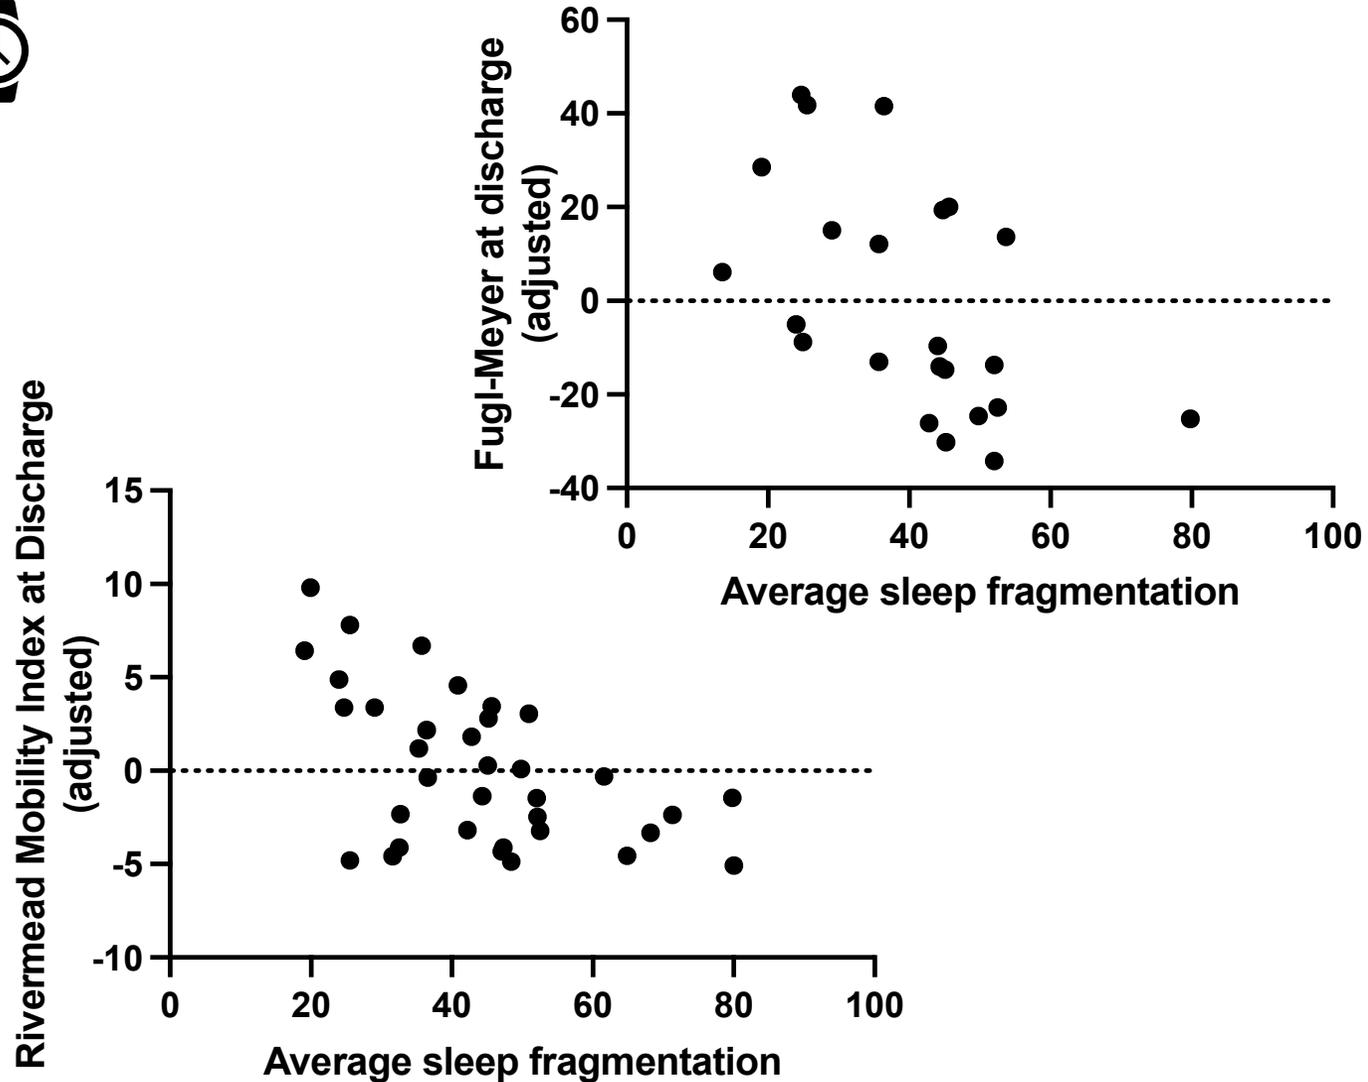

Pain

Co-morbidities

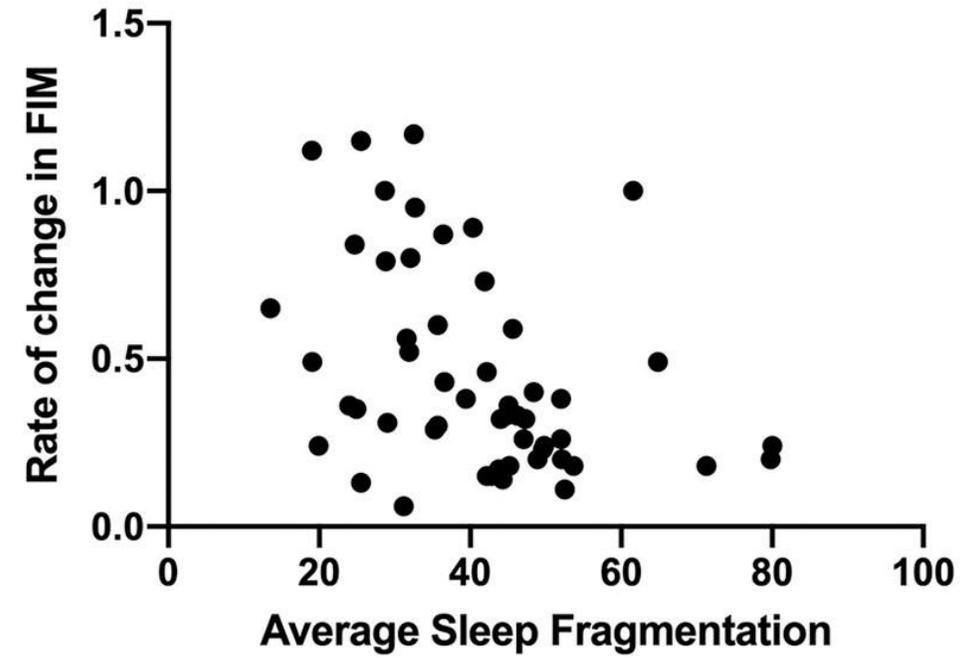

Sleep after Stroke

← = less disrupted sleep

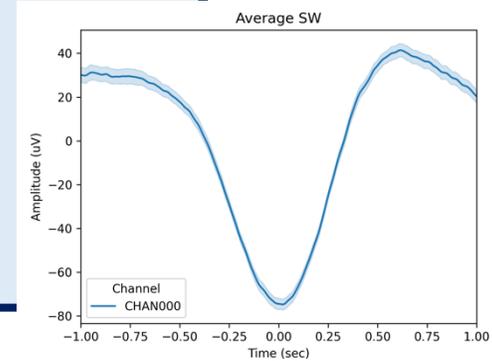

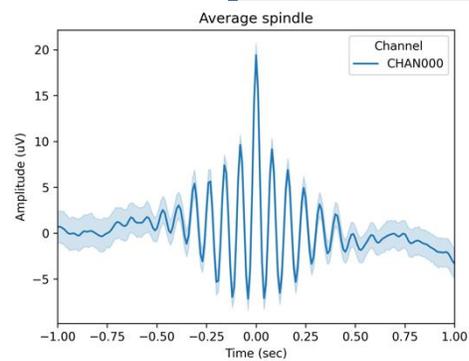

↑ = better motor outcome

Demographics

82

Consented

58

Complete

22

Ongoing

16

Withdrawn

Average age: 72.0 (43-91 yrs)

Sex: Male (45); Female (37)

NIHSS: 7.8 (1-24)

PREP2 scores: Poor (11); Limited (8); Good (26);
Excellent (37)

Stroke type: Ischemic (68); Haemorrhagic (14)

Stroke laterality: Right (43); Left (37); Unknown (2)

Handedness: Right (74); Left (8)

mRS: 2.9 (1-5)

SCI: 22.0 (2-32)

PHQ8: 5.6 (0-19)

Stop-Bang: 3.7 (1-7)

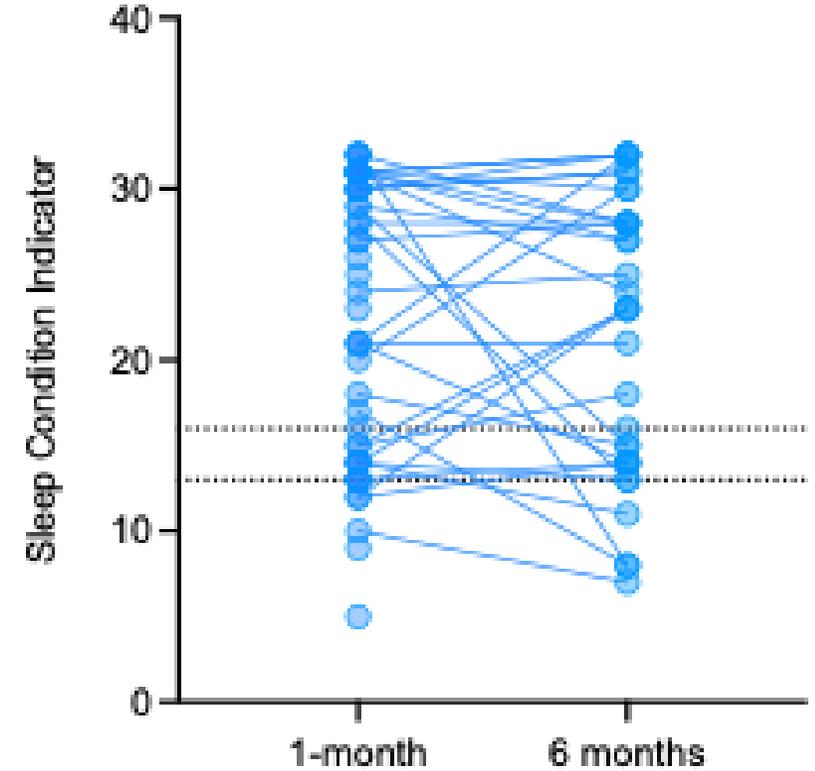

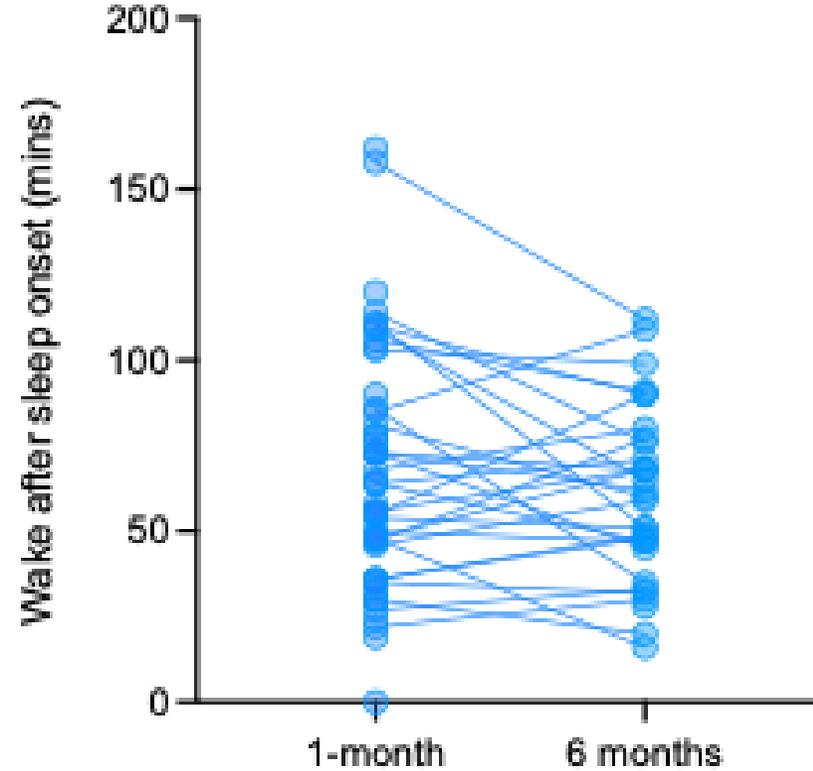

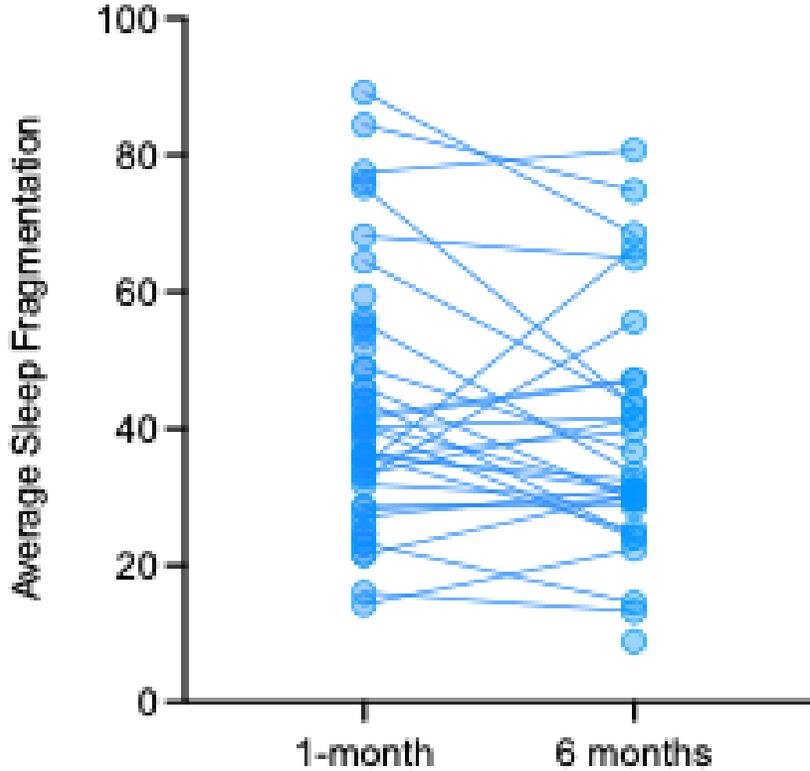

Sleep

↓ = less disrupted sleep

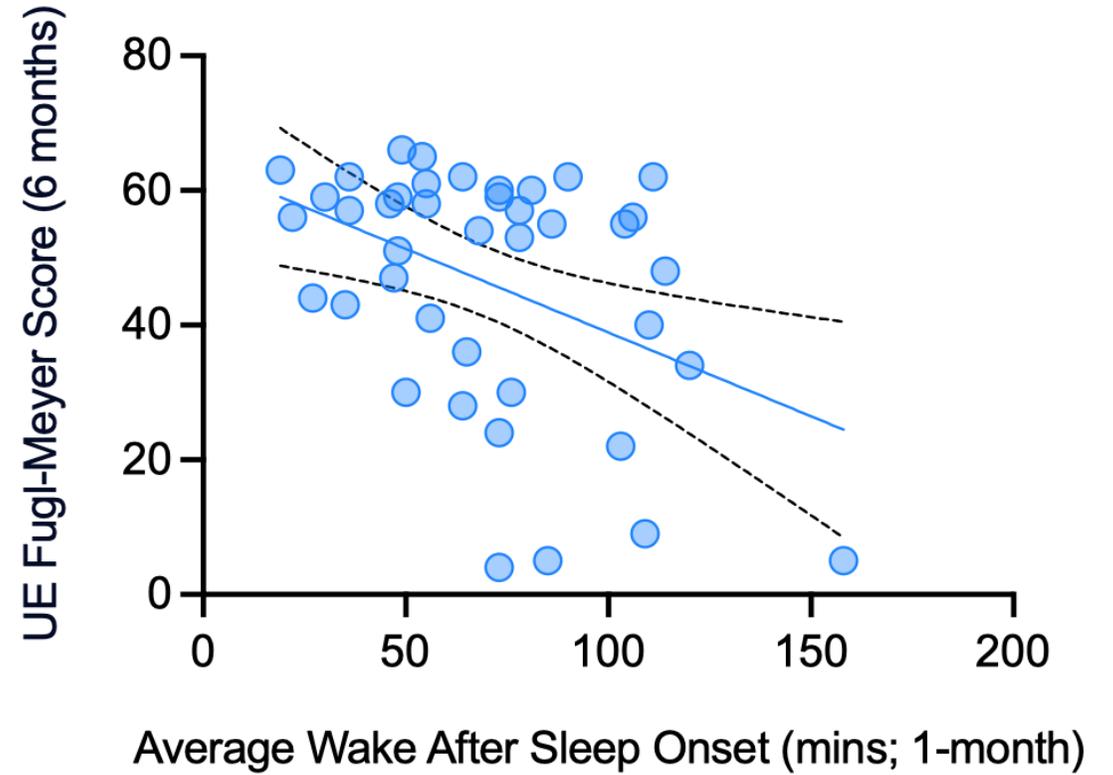

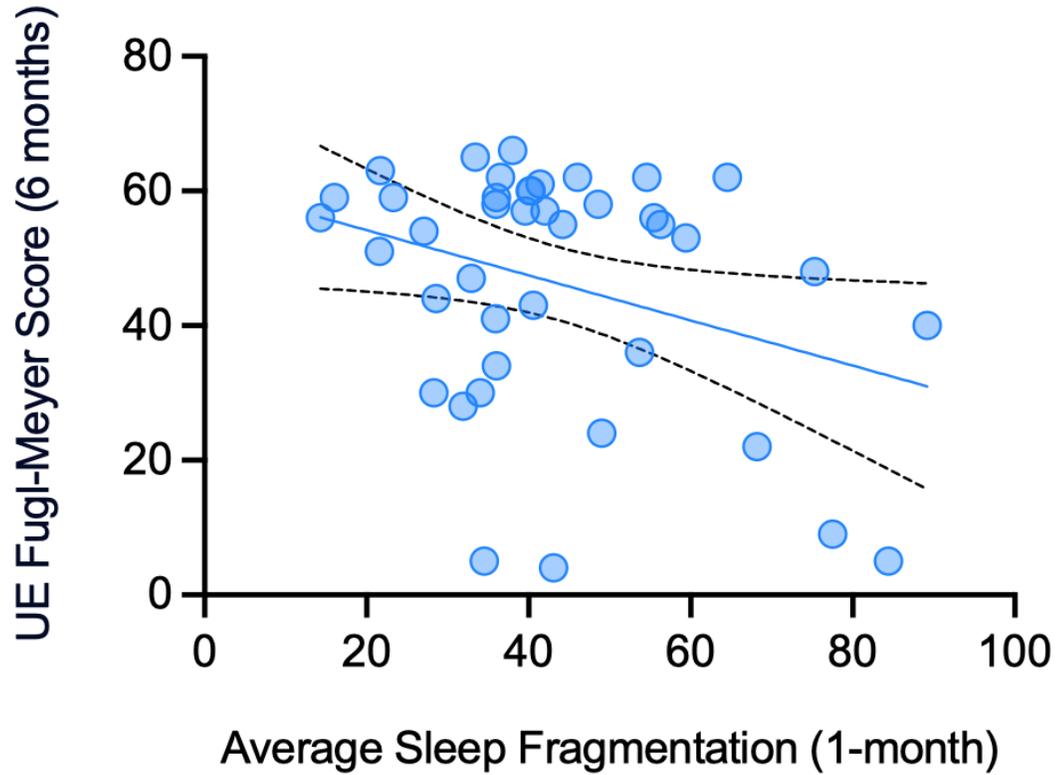

↑ = better self-reported sleep

Sleep & Recovery

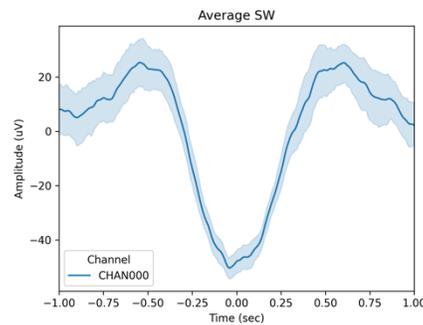

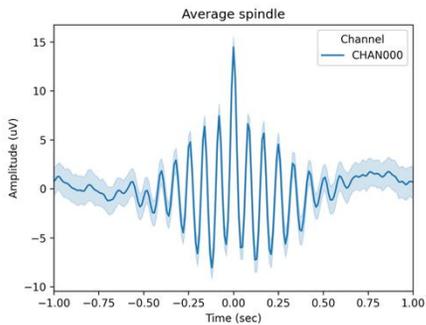

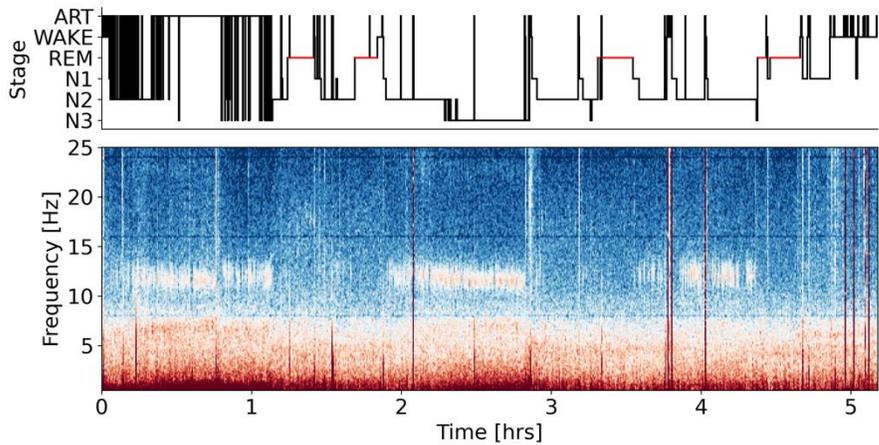

↩ = less disrupted sleep, ↑ = better function

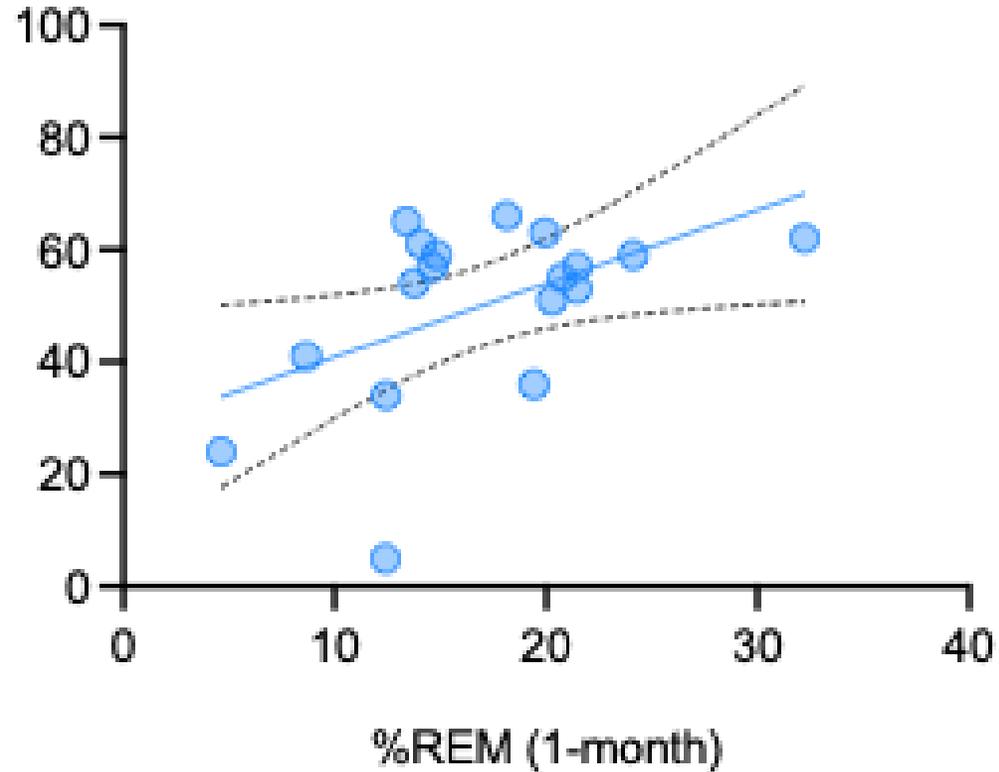

Sleep & Recovery

⇒ = more REM sleep, ↑ = better function

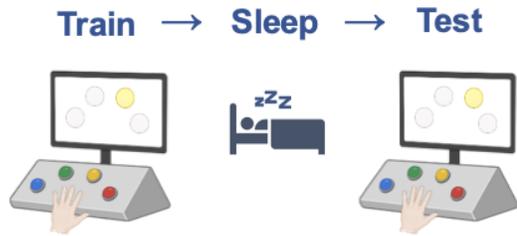

UE Fugl-Meyer Score (6 months)

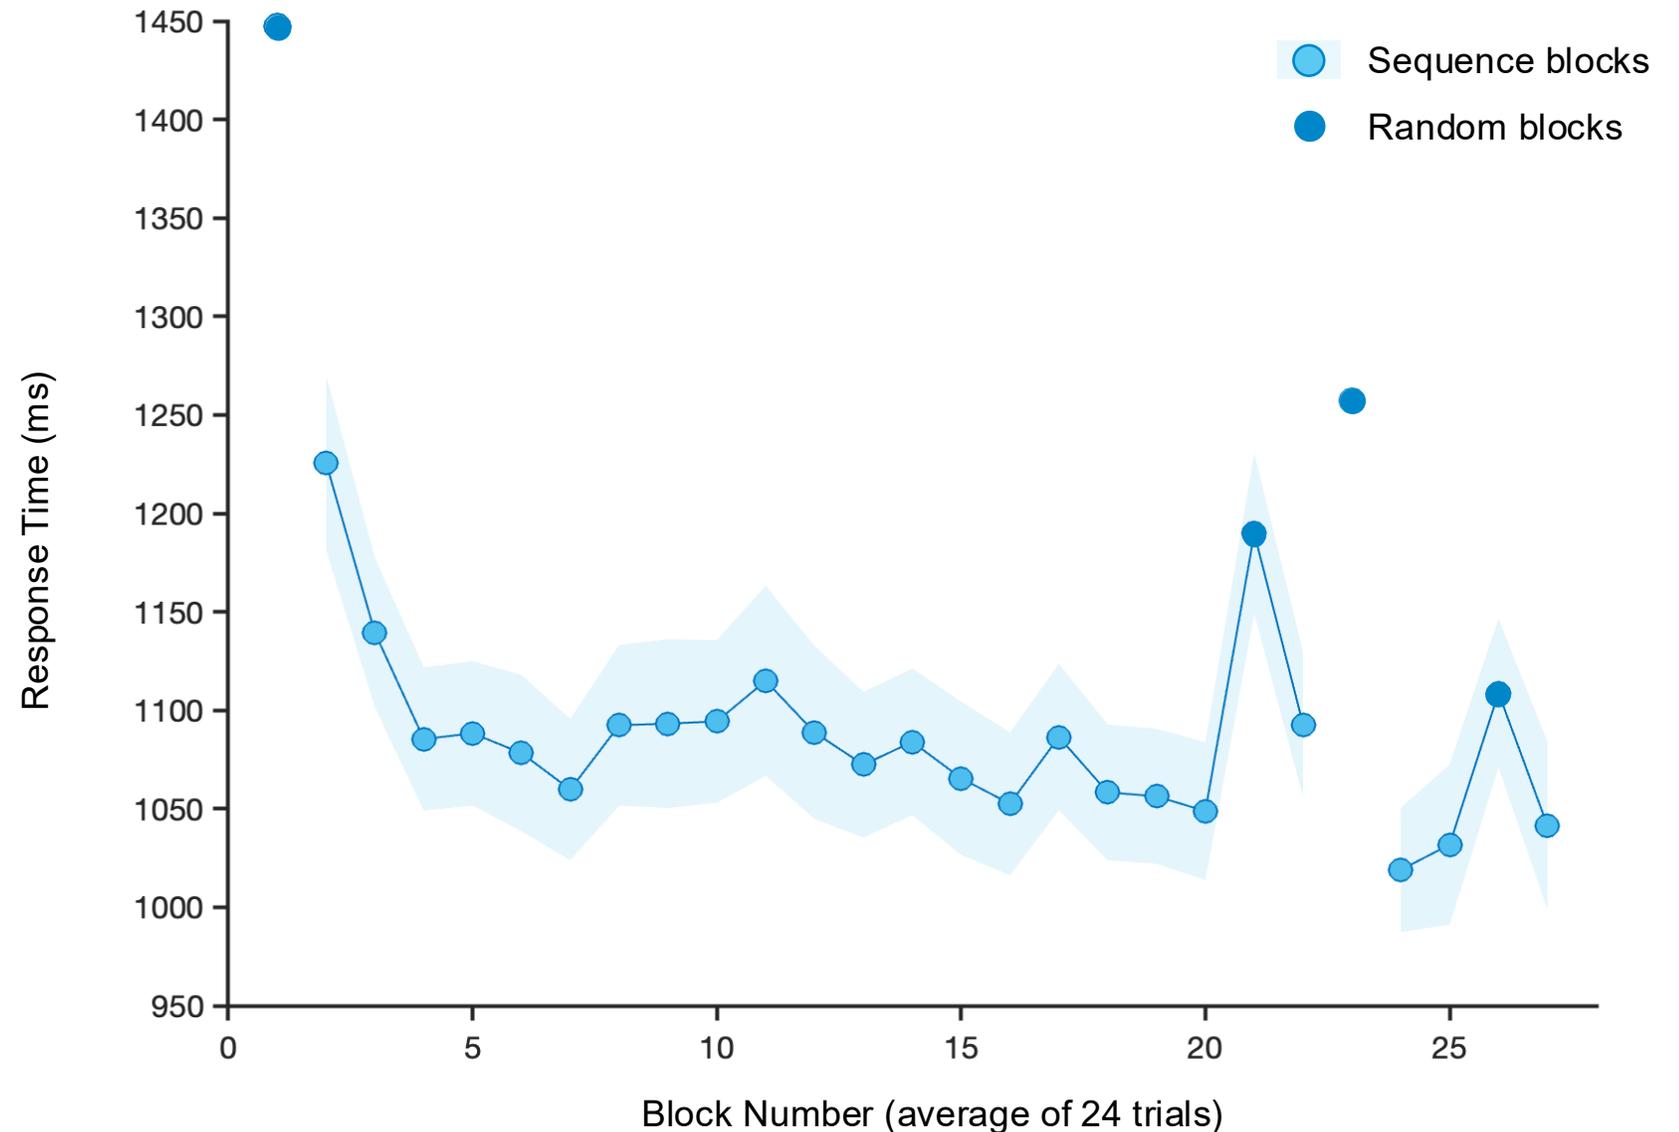

- Preliminary (& exploratory) indication that more REM sleep may be important to recovery processes.
- No current associations with any aspects of NREM sleep.

Motor Consolidation

n = 40 (~1-month post-stroke)

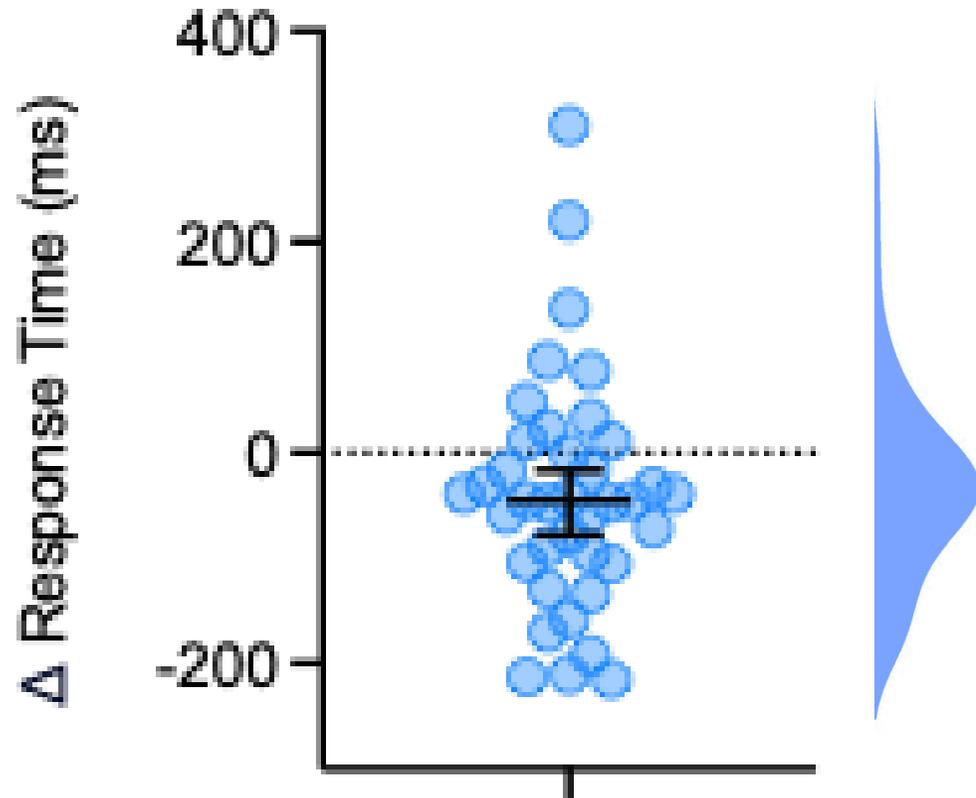

- 12-item sequence
- **Training:**
2 Random Blocks;
20 Sequence Blocks
- **Test:**
2 Random Blocks;
3 Sequence Blocks

Motor Consolidation

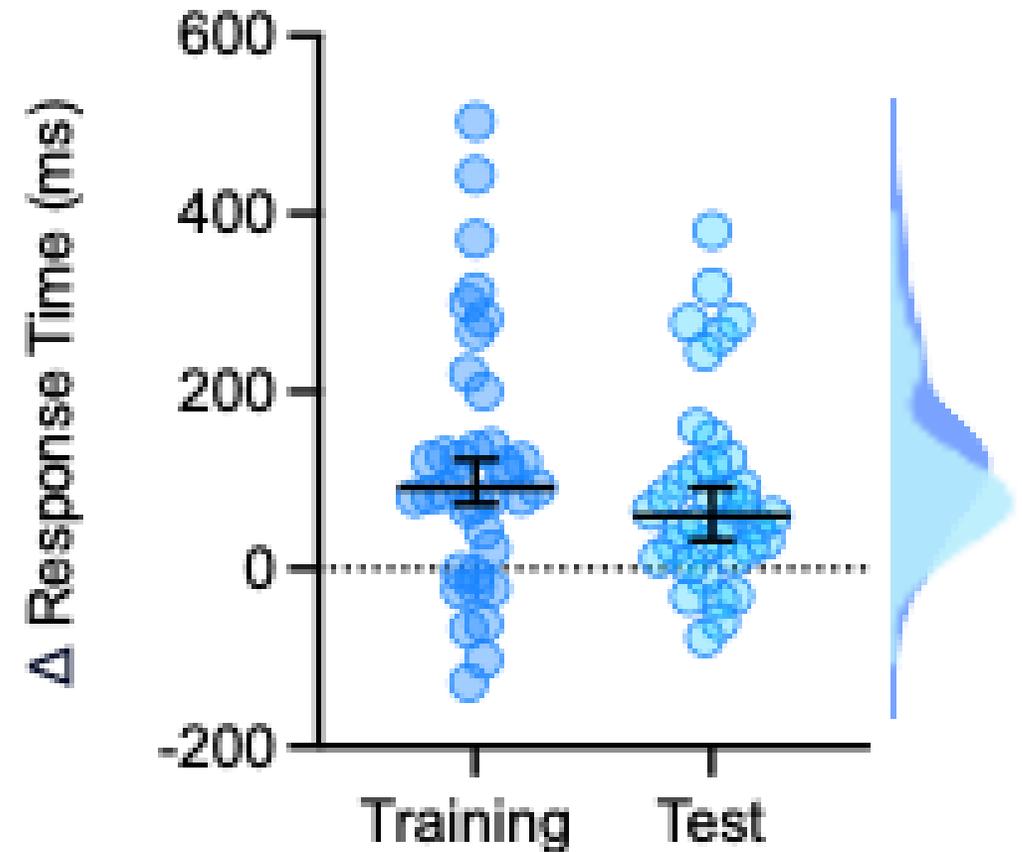

Overnight Consolidation

↓ = more consolidation

Sequence Specificity

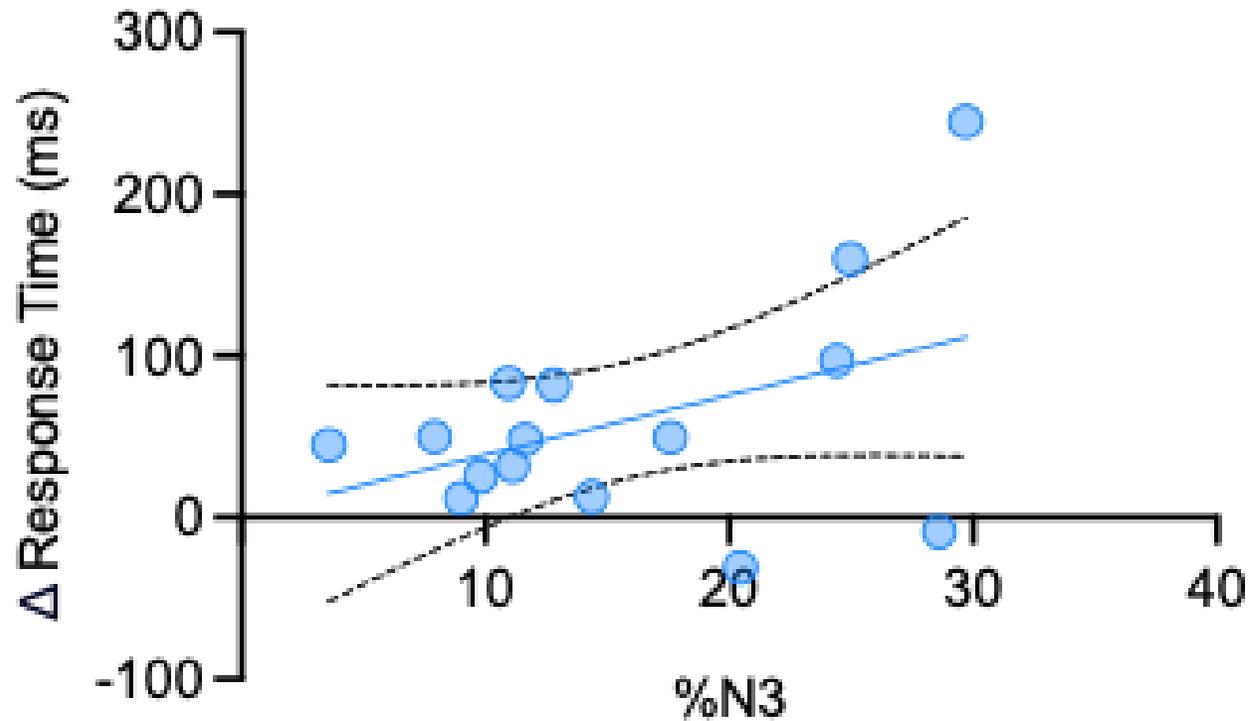

↑ = better sequence encoding

Motor Consolidation

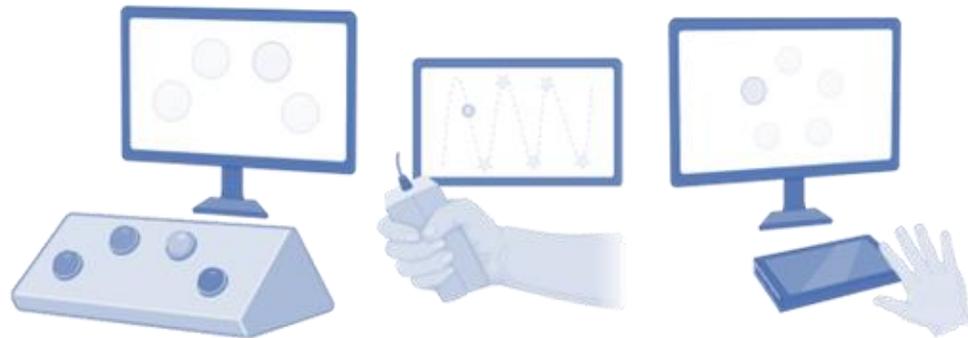

↑ = better sleep-dependent sequence encoding

- Preliminary indication that more time spent in N3 (slow-wave sleep) may lead to better sequence encoding at re-test.
- Further analysis will endeavour to identify correlates with sleep microarchitecture e.g., sleep spindles, slow oscillations, and their temporal coupling

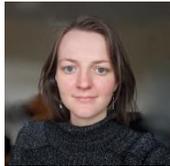

Conclusions

- Taken together, these multimodal findings suggest that sleep disruption is not merely a symptom of stroke but a potential mechanistic barrier to motor recovery.
- By linking behavioural consolidation, sleep physiology, and MRI, this work highlights sleep as an under recognised but modifiable target for potentially improving rehabilitation outcomes.
- Future interventions aimed at improving sleep quality and/or enhancing specific sleep physiology may offer a novel pathway to strengthen motor consolidation and promote functional gains after stroke.
